#### Abstract

The path VC-dimension of a graph $G$ is the size of the largest set $U$ of vertices of $G$ such that each subset of $U$ is the intersection of $U$ with a subpath of $G$. The VC-dimension for graphs was introduced by Kranakis, et al. [KKR $\left.{ }^{+} 97\right]$, building on an idea of Haussler and Welzl [HW87]. We show that computing the path VC-dimension of a graph is $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathbf{p}}$-complete. This adds a rare natural $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathbf{p}}$-complete problem to the repertoire.

## 1 Introduction

A set system $\mathcal{C}$ is said to shatter a set $A$ if for each subset $S$ of $A$ there is a set $C \in \mathcal{C}$ such that $S=A \cap C$. If $\mathcal{C}$ shatters a set of cardinality $k$ we say that $\mathcal{C}$ has Vapnik-Červonenkis-dimension (VC-dimension) at least $k$. The VC-dimension was introduced by Vapnik and Červonenkis in their study of uniform convergence of relative frequencies. It has become a successful tool in areas such as computaional learning theory, and computational geometry [AB92, HW87]. Roughly speaking, it is used to measure the complexity of set systems. For example, the VC-dimension of a concept class is finite precisely if the class is learnable in the PAC-learning model, and the VC-dimension of the class can be used to determine the necessary sample size. It is not surprising then that the complexity of computing the VC-dimension has received some attention. The complexity depends on the model, i.e. how the set system is represented as an input. Several different models have been studied in the literature; to mention just two examples: if the set system $\mathcal{C}$ is represented as a matrix, then determining the VC dimension is LOGNP-complete [PY93], if it the set system is represented by a circuit, the problem is $\boldsymbol{\Sigma}_{3}^{\mathrm{p}}$-complete [Sch99b].

Haussler and Welzl [HW87] introduced the VC-dimension of a graph; the set to be shattered is a set of vertices of the graph, and $\mathcal{C}$ is the collection of neighborhoods of vertices in the graph [HW87, ABC95]. In a recent paper, Kranakis, Krizanc, Ruf, Urrutia, and Woeginger [KKR $\left.{ }^{+} 97\right]$ generalized this definition from neighborhoods of vertices to allow arbitrary collections of subgraphs. They determined the computational complexity of several of these problems, showing, for example, that deciding whether at least $k$ vertices in a graph are shattered by subtrees of the graph is NP-complete. The main open problem left by that paper was the case in which $\mathcal{C}$ is the set of all subpaths of the graph, the path $V C$-dimension of the graph. The paper showed that the decision problem is NP-hard leaving a large
gap to $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathbf{p}}$ which is a natural upper bound for the problem. We close the gap by showing the problem $\Sigma_{3}^{\mathrm{p}}$-complete.
Theorem 1.1 Deciding the path Vapnik-Červonenkis-dimension of a graph is $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathrm{p}}$-complete.
This is a companion result to the earlier result that determining the VC-dimension in the circuit model is $\boldsymbol{\Sigma}_{3}^{\mathrm{p}}$-complete [Sch99b]. Despite the similarity in the statements of the two problems, the proofs are completely independent. The reason is the difference in models. A direct reduction from one problem to the other would probably be much more complicated than the approach through quantified Boolean formulas taken here.

Completeness proofs for higher levels of the polynomial hierarchy are surprisingly rare. Recent progress includes problems in learning theory, logic and Ramsey theory [Uma98, Sch99b, Sch99a, Uma99].

## 2 VC-Dimension of Graphs

Let $F=(V, E)$ be a graph, and $\mathcal{C}$ a collection of subgraphs of $F$. We say that $\mathcal{C}$ shatters a set of vertices $W$ of $F$ if for all $W^{\prime} \subseteq W$ there is a graph $G \in \mathcal{C}$ such that $G$ contains all the vertices in $W^{\prime}$, but none of the vertices in $W \backslash W^{\prime}$. We define the $V C$-dimension of $\mathcal{C}$ with respect to $F$ as

$$
\mathrm{V} C_{\mathcal{C}}(F)=\max \{|W|: W \text { is shattered by } \mathcal{C}\}
$$

if $\mathcal{C} \neq \emptyset$, and let $\mathrm{VC}_{\emptyset}(F)=-1$, otherwise. Note that the definition of $\mathrm{V} C$ makes sense for both directed, and undirected graphs.

For any property $\mathcal{P}$ of graphs we will write $\mathrm{VC}_{\mathcal{P}}(F)$ for $\mathrm{V} C_{\mathcal{C}}(F)$ where $\mathcal{C}=\{G: G$ is a subgraph of $F$ with property $\mathcal{P}\}$. Thus we have $\mathrm{VC}_{\text {path }}, \mathrm{VC}_{c y c l}$, for example, and the corresponding decision problems. For directed graphs $F$, we also require the paths and cycles to be directed.

## GRAPH VC path DIMENSION

Instance: (Finite) graph $F$, number $k$.
Question: $\mathrm{VC}_{\text {path }}(F) \geq k$ ?

## DIGRAPH VC path DIMENSION

Instance: (Finite) directed graph $F$, number $k$.
Question: $\mathrm{VC}_{\text {path }}(G) \geq k$ ?

The complexity of GRAPH $\vee^{\prime} C_{P}$ DIMENSION depends on the property $\mathcal{P}$. It is simple to construct properties $\mathcal{P}$ for which GRAPH $\mathrm{VC}_{P}$ DIMENSION is undecidable, but such properties are hardly natural properties of graphs.
Lemma 2.1 $V C_{\mathcal{P}}$ can be decided in $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathrm{p}}$ if $\mathcal{P}$ can be verified in $\mathbf{N P}$.
Proof. $\quad V C_{\mathcal{P}}(F) \geq k$ is equivalent to saying that there is a set $W$ of $k$ vertices of $F$ such that for every subset $S$ of $W$ there is a subgraph $G$ of $F$ such that $\mathcal{P}(F)$ is true, and $G$ contains all vertices in $S$, but no vertex in $W-S$.

We conclude that GRAPH ${V C_{p a t h}}$ DIMENSION, DIGRAPH VC $C_{p a t h}$ DIMENSION, GRAPH VC ${ }_{c y c l e}$ DIMENSION, and DIGRAPH $\mathrm{VC}_{c y c l e}$ DIMENSION all lie in $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathbf{p}}$. Table 1 summarizes the known complexity result.

For trees $\mathrm{VC}_{\text {tree }}=\mathrm{VC}_{\text {connected }}$ implies NP-completeness $\left[\mathrm{KKR}^{+} 97\right]$. We obtain a nonapproximability result from a simple construction.
Theorem 2.2 If $f$ is a function for which $\left|f(F)-\mathrm{V} C_{\text {path }}(F)\right|=o\left(|F|^{1 / 2}\right)$, then $\mathrm{V}_{\text {path }}$ can be computed from $f$ in polynomial time with one query.

| Property $\mathcal{P}$ | Computational Complexity |  | Reference |

| cycles |  | Corollary 3.3 |  |

Figure 1: Complexity of $\mathrm{V} C_{\mathcal{P}}$

This implies that approximating $\mathrm{V} C_{p a t h}$ to within an additive constact of $o\left(n^{1 / 2}\right)$ is still $\boldsymbol{\Sigma}_{\mathbf{3}^{-}}^{\mathrm{p}}$ complete. The proof follows immediately from the following lemma.
Lemma 2.3 Given a graph $F$ we can construct a graph $G$ such that $\mathrm{VC}_{\text {path }}(G)=|F| \mathrm{VC}_{\text {path }}(F)$, and $|G|=O\left(|F|^{2}\right)$.

Proof. Take $|F|$ copies $F_{1}, \ldots, F_{|F|}$ of $F$, and $|F|-1$ new vertices $v_{1}, \ldots, v_{|F|-1}$. We add edges from $v_{i}$ to all vertices of $F_{i}$, and $F_{i+1}(1 \leq i<|F|)$. We claim that the resulting graph $G$ fulfills $\mathrm{V} C_{\text {path }}(G)=|F| \mathrm{VC}_{\text {path }}(F)$. We immediately have $\mathrm{V} C_{p a t h}(G) \geq|F| \mathrm{V} C_{p a t h}(F)$ from the construction. To show the other direction, assume we have a set $W$ of $|F| \mathrm{V} C_{p a t h}(F)+1$ vertices shattered by paths. First note that $W$ cannot contain any of the vertices $v_{i}$ (since they disconnect $G$, hence all of $W$ would have to lie on one side of it). Hence $W$ contains $\mathrm{VC}_{\text {path }}(F)+1$ vertices in some $F_{i}$. However, this implies that these $\mathrm{V} C_{\text {path }}(F)+1$ are shattered by paths within $F_{i}$ which contradicts $\mathrm{VC}_{\text {path }}\left(F_{i}\right)=\mathrm{V} C_{\text {path }}(F)$. $\diamond$

## 3 Paths and Cycles

Our goal is to show that computing the path VC-dimension is $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathrm{p}}$-complete. We approach this goal in two steps: we first show that computing the (directed) cycle VC-dimension for directed graphs is $\Sigma_{3}^{\mathrm{p}}$-complete, and we then show how to modify the proof for paths, and then for undirected graphs.

## Lemma 3.1 DIGRAPH $\mathrm{VC}_{\mathrm{cycle}}$ DIMENSION is $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathrm{p}}$-complete.

Proof. We will show how to reduce QSAT ${ }_{3}$, the standard $\boldsymbol{\Sigma}_{3}^{\mathrm{p}}$-complete problem to DIGRAPH VC $\mathrm{c}_{\mathrm{cycle}}$ DIMENSION. Combined with Lemma 2.1 this proves the result.

Suppose we are given an instance of QSAT ${ }_{3}$, that is a formula $\Psi$ of the form $(\exists a)(\forall b)(\exists c) \Phi(a, b, c)$, where $\Phi$ is a boolean expression in CNF and the variables in $\Phi$ are partitioned into three sets $X_{1}, X_{2}$, and $X_{3}$. The strings $a, b$ and $c$ are assignments to variables in these sets, rsp.

We build on a construction that shows that deciding whether a directed graph contains a Hamiltonian cycle is $\boldsymbol{\Sigma}_{1}^{\mathrm{p}}$-complete. We refer the reader to the construction in Hopcroft and Ullmann's book [HU79, Section 3.2] which gives us the following: for each quantifier-free formula $\Phi$ we can construct in polynomial time a graph $F=F_{\Phi}$ with the following properties:

- for each variable $x$ of $\Phi, F_{\Phi}$ contains three vertices $u_{x}, v_{x}$, and $w_{x}$ and edges $\left(u_{x}, v_{x}\right),\left(u_{x}, w_{x}\right)$, $\left(v_{x}, w_{x}\right)$, and $\left(w_{x}, v_{x}\right)$ (and no other edges between these three vertices),
- if the truth-assignment $t$ (mapping variables of $\Phi$ to $\{\perp, \top\}$ ) makes $\Phi$ true, then there is a Hamiltonian cycle which includes the edge $\left(u_{x}, v_{x}\right)$ if $t(x)=\perp$, and the edge $\left(u_{x}, w_{x}\right)$ otherwise, and
- if $\Phi$ has no satisfying truth-assignment, then $F_{\Phi}$ does not contain a Hamiltonian cycle.

We will now modify $F$ to fit our purposes in two steps.
In a first step we change the triangle associated with each variable. Let $G$ be the graph obtained from $F$ as follows: for each $x \in X_{1}$ we add two new vertices $v_{x}^{\prime}$, and $w_{x}^{\prime}$ together with edges $\left(u_{x}, v_{x}^{\prime}\right)$, $\left(v_{x}^{\prime}, v_{x}\right),\left(u_{x}, w_{x}^{\prime}\right),\left(w_{x}^{\prime}, w_{x}\right)$. For each $x \in X_{2}$ we add one new vertex $v_{x}^{\prime}$, remove the edge $\left(u_{x}, v_{x}\right)$, and add two edges $\left(u_{x}, v_{x}^{\prime}\right)$, and $\left(v_{x}^{\prime}, v_{x}\right)$. We do not make any changes to the triangles associated with variables from $X_{3}$.

In the graph $G$ let us distinguish between the vertices $V_{1}$ originally from $F$, and the vertices $V_{2}$ which were added to $F$ in the construction of $G$. Let $\mathcal{C}$ be the collection of cycles in $G$ that pass through all vertices in $V_{1}$. We claim that
$\Psi$ is true if and only if $\operatorname{V} C_{\mathcal{C}}(G) \geq n$,
where $n=\left|X_{1}\right|+\left|X_{2}\right|$. Let us verify the claim. If $\Psi$ is true, then there is an assignment $a$ to the variables in $X_{1}$ such that for all assignments $b$ to variables in $X_{2}$ there is an assignment $c$ to variables in $X_{3}$ such that $\Phi(a, b, c)$ is true. Fix such an $a$. Let

$$
U=\left\{v_{x}^{\prime}: a(x)=\top, x \in X_{1}\right\} \cup\left\{w_{x}^{\prime}: a(x)=\perp, x \in X_{1}\right\} \cup\left\{v_{x}^{\prime}: x \in X_{2}\right\}
$$

First notice that $|U|=\left|X_{1}\right|+\left|X_{2}\right|$. We claim that $U$ is shattered by $\mathcal{C}$ which immediately implies $\mathrm{V} C_{\mathcal{C}}(G) \geq n$. Let $U^{\prime} \subseteq U$ be an arbitrary subset of $U$. Define a truth assignment $b$ for $x \in X_{2}$ by $b(x)=\top$ if $v_{x}^{\prime} \in U^{\prime}$, and $b(x)=\perp$ otherwise. Having $a$ and $b$ there is a truth assignment $c$ to the variables in $X_{3}$ such that $\Phi(a, b, c)$ is true. Corresponding to the truth assignment is a Hamiltonian cycle through $F$ that for each variable $x$ passes through $v_{x}$ if and only if $x$ has been assigned the value true (otherwise it passes through $w_{x}$ ). We can now extend this Hamiltonian cycle to $G$ in such a way that it contains all vertices in $U^{\prime}$ and no vertex in $U \backslash U^{\prime}$. Since $U^{\prime}$ was chosen as an arbitrary subset of $U$, and $|U|=n$ this shows that $\mathrm{V}_{\mathcal{C}}(G) \geq n$.

To show the other direction assume that $\operatorname{V} C_{\mathcal{C}}(G) \geq n$. Let $U$ be a set of $n$ vertices of $G$ that is shattered by $\mathcal{C}$. Note that for each vertex $x \in X_{1}$ at most one of $v_{x}^{\prime}$ and $w_{x}^{\prime}$ can be in $U$ (there is no path from one to the other). Since $\left|X_{1}\right|+\left|X_{2}\right|=n$, and $U \subseteq\left\{v_{x}^{\prime}, w_{x}^{\prime}: x \in X_{1}\right\} \cup\left\{v_{x}^{\prime}: x \in X_{2}\right\}$ we can conclude that $U$ contains all of $\left\{v_{x}^{\prime}: x \in X_{2}\right\}$ and exactly one vertex from each pair $\left\{v_{x}^{\prime}, w_{x}^{\prime}\right\}$ where $x \in X_{1}$. Define $a(x)=\top$ if $v_{x}^{\prime} \in U$ for $x \in X_{1}$, and $a(x)=\perp$ otherwise. Let $b$ be an arbitrary truth assignment to the vertices in $c$. Now define $U^{\prime}=\left\{v_{x}^{\prime}: a(x)=\top, x \in X_{1}\right\} \cup\left\{w_{x}^{\prime}: a(x)=\perp, x \in\right.$ $\left.X_{1}\right\} \cup\left\{v_{x}^{\prime}: b(x)=\top, x \in X_{2}\right\}$. Then $U^{\prime}$ is a subset of $U$ (by the choice of $a$ ). Hence there is a cycle $C$ through $G$ which contains all vertices in $V_{1}$ and $U^{\prime}$, and no vertex from $U \backslash U^{\prime}$. If $C$ passes through $v_{x}^{\prime}$ for some $x \in X_{1}$ it also has to pass through $v_{x}$, and similarly it will pass through $w_{x}$ if it passes through $w_{x}^{\prime}$. If $C$ passes through $v_{x}^{\prime}$ for some $x \in X_{2}$ it will pass through $v_{x}$, and if it does not pass through $v_{x}^{\prime}$ it will have to pass through $w_{x}$. Hence if we restrict $C$ to $F$ we get a Hamiltonian cycle that corresponds to a truth assignment to $\Phi$ that extends $a$ and $b$ to the variables of $X_{3}$. Since $b$ was chosen arbitrarily this implies that $\Psi$ is true.

We have showed that $\Psi$ is true if and only if $\operatorname{VC} C_{\mathcal{C}}(G) \geq n$, where $n=\left|X_{1}\right|+\left|X_{2}\right|$.
Remember that the vertices of $G$ are partitioned into $V_{1}$ (those contained in all $\mathcal{C}$ ) and $V_{2}$ (subsets of which are shattered by $\mathcal{C}$ ). We now obtain $H$ from $G$ by splitting each vertex $v \in V_{1}$ of $G$ into two vertices $v_{1}$ and $v_{2}$ such that $v_{1}$ has only incoming edges, and $v_{2}$ only outgoing edges. For each vertex $v \in V_{1}$ we add a new copy of a clique $K_{m}$ (where $m=2|G|$ ) and add edges from $v_{1}$ to each vertex of
$K_{m}$, and edges from each vertex of $K_{m}$ to $v_{2}$. Finally we include an edge from $v_{1}$ to $v_{2}$. We say that the clique is associated with $v$. No changes to the vertices in $V_{2}$ are necessary.

If $\mathrm{V} C_{\mathcal{C}}(G) \geq 0$, then $\mathrm{V} C_{c y c l e}(H) \geq m\left|V_{1}\right|+\mathrm{V} C_{\mathcal{C}}(G)$. This is immediate from the construction of $H$ : let $U$ be a set of $\mathrm{VC}_{\mathcal{C}}(G)$ vertices shattered by $\mathcal{C}$ in $G$. Obviously $U \subseteq V_{2}$ (since the vertices in $V_{1}$ belong to each path in $\mathcal{C}$. Then the $\left|V_{1}\right|$ cliques $K_{m}$ that are associated with vertices in $V_{1}$ together with the $\operatorname{V} C_{\mathcal{C}}(G)$ in $U$ (as vertices in $H$ ) are shattered by cycles in $H$. This follows from the construction: for the cliques in $V_{1}$ note that we can skip them by the edge from $v_{1}$ to $v_{2}$, and we can skip a clique associated with a vertex $v_{x}^{\prime}$ or $w_{x}^{\prime}$ in $V_{2}$ because we can avoid that vertex in $G$.

Now suppose that $\mathrm{V}_{c y c l e}(H)>m\left|V_{1}\right|+\mathrm{V} C_{\mathcal{C}}(G)$. Let $U$ be a set of $\mathrm{V}_{c y c l e}(H)$ vertices shattered in $H$ by cycles. We first note that $U$ contains vertices in all cliques $K_{m}$ associated with vertices in $V_{1}$. If that was not the case, the size of $U$ would be at most $m\left(\left|V_{1}\right|-1\right)+2\left|V_{1}\right|+\left|V_{2}\right| \leq m\left(\left|V_{1}\right|-1\right)+2|G| \leq m\left|V_{1}\right|$ contradicting $|U|=\mathrm{V} C_{c y c l e}(H)>m\left|V_{1}\right|+\mathrm{V} C_{\mathcal{C}}(G)$. Let $\mathcal{D}$ be the set of cycles in $H$ that pass through every vertex in every clique associated with a vertex in $V_{1}$. Since $U$ contains vertices in all these cliques, we can conclude that

$$
\mathrm{V} C_{\mathcal{D}}(H)>\mathrm{V} C_{\mathcal{C}}(G)
$$

Let $U^{\prime}$ be the set of $\operatorname{V} C_{\mathcal{D}}(H)$ vertices shattered by $\mathcal{D}$ in $H$. First note that $U^{\prime} \subseteq V_{2}$. This is because $\mathcal{D}$ contains all the vertices in the cliques associated with $V_{1}$, and hence it cannot contain any of the vertices $v_{1}, v_{2}$ for $v \in V_{1}$ (if it contained $v_{1}$, then we cannot avoid $v_{1}$ and contain a vertex in the corresponding clique, if it contained $v_{2}$ it has to contain a vertex in the corresponding clique). But this implies that $\mathrm{V} C_{\mathcal{D}}(H)=\mathrm{V} C_{\mathcal{C}}(G)$, a contradiction, establishing $\mathrm{V} C_{c y c l e}(H) \leq m\left|V_{1}\right|+\mathrm{V} C_{\mathcal{C}}(G)$.

We conclude that $\mathrm{V} C_{c y c l e}(H)=m\left|V_{1}\right|+\mathrm{V} C_{\mathcal{C}}(G)$ if $\mathrm{V} C_{\mathcal{C}}(G) \geq 0$. Combining the two steps of the construction yields that $\Psi$ is true if and only if $\operatorname{VC_{\mathcal {C}}}(G) \geq n$ if and only if $\mathrm{VC}_{\text {cycle }}(H) \geq m\left|V_{1}\right|+n$ (note that $n \geq 0$ ). This shows that QSAT ${ }_{3}$ reduces to DIGRAPH $\mathrm{VC}_{c y c l e}$ DIMENSION.

## Corollary 3.2 DIGRAPH $\vee_{\mathrm{p} \text { ath }}$ DIMENSION is $\boldsymbol{\Sigma}_{3}^{\mathrm{p}}$-complete.

Proof. This is a corollary to the proof of Lemma 3.1. The original graph $F$ contains an edge $(u, v)$ that all Hamiltonian cycles of $F$ pass through. This edge is still present in $H$, and all the cycles in a set of cycles shattering $\mathrm{VC}_{\text {cycle }}(H)$ vertices pass through this edge. Construct a new graph $H^{\prime}$ from $H$ by removing the edge $(u, v)$, and adding two copies of a $K_{n}$ (with $n>|H|$ ). Furthermore add edges from one of the $K_{n}$ to $u$, and edges from $v$ to the other. Then $\mathrm{VC}_{p a t h}\left(H^{\prime}\right)=\mathrm{V} C_{c y c l e}(H)+2 n$, hence computing $\mathrm{VC}_{\text {path }}$ on directed graphs is $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathbf{p}}$-complete.
Corollary 3.3 GRAPH $\mathrm{VC}_{\text {cycle }}$ DIMENSION is $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathrm{p}}$-complete.
Proof. Consider the graph $H$ constructed in the proof of Lemma 3.1, and let $H^{\prime}$ be the undirected graph we get from $H$ by removing the direction of edges in $H$. We claim that

$$
\mathrm{V} C_{c y c l e}(H)=\mathrm{V} C_{c y c l e}\left(H^{\prime}\right)
$$

This, of course, is not true in general and depends on the particular structure of the graph. We have to show that $\mathrm{V} C_{\text {cycle }}(H) \geq \mathrm{V} C_{c y c l e}\left(H^{\prime}\right)$. Assume for a contradicion that $\mathrm{V} C_{c y c l e}\left(H^{\prime}\right)>m\left|V_{1}\right|+\mathrm{V} C_{\mathcal{C}}(G)$. As in Lemma 3.1 we conclude that

$$
\mathrm{V} C_{\mathcal{E}}\left(H^{\prime}\right)>\mathrm{V} C_{\mathcal{C}}(G)
$$

where $\mathcal{E}$ now is the set of undirected cycles in $H^{\prime}$ that pass through each vertex in every clique associated with vertices in $V_{1}$ (this was a pure counting argument, not depending on the direction of edges). Now consider a cycle $C$ in $\mathcal{E}$. For any vertex $v \in V_{1}$ the cycle $C$ has to contain both $v_{1}$ and $v_{2}$ since it contains all vertices in the associated clique, and it has to enter and exit the clique, for which only $v_{1}$
and $v_{2}$ are available. Furthermore vertices $v \in V_{2}$ all of degree two (one incoming, one outgoing edge in $H$ ). This means that to $C$ corresponds a directed cycle $D$ in $H$ containing all $v \in V_{1}$, and $v \in V_{2}$ if and only if $v \in C$. Therefore $\mathrm{VC}_{\mathcal{E}}\left(H^{\prime}\right)=\mathrm{V} C_{\mathcal{D}}(H)=\mathrm{V} C_{\mathcal{C}}(G)$ (the latter equation by the proof of Lemma 3.1) which contradicts our assumption.

Repeating the argument of Corollary 3.2 we obtain the result we were looking for.
Corollary 3.4 GRAPH $\mathrm{VC}_{\text {path }}$ DIMENSION is $\boldsymbol{\Sigma}_{3}^{\mathrm{p}}$-complete.
