October 5, 2008

#### Abstract

We present a Garey/Johnson-style list of problems known to be complete for the second and higher levels of the polynomial-time Hierarchy (polynomial hierarchy, or $\mathbf{P H}$ for short). We also include the best-known hardness of approximation results. The list will be updated as necessary.

## Updates

The compendium currently lists more than 80 problems. Latest changes include:

- added [GT26] SUCCINCT $k$-KING,
- added [GT25] SUCCINCT $k$-DIAMETER,
- added [GT4] SUCCINCT $k$-RADIUS at third level,
- added [GT24] MINIMUM VERTEX COLORING DEFINING SET,
- added [GT23] GRAPH SANDWICH PROBLEM FOR $\Pi$,
- added [L24] MINIMUM 3SAT DEFINING SET,
- added [L23] $\exists \exists_{t}!$ 3SAT,
- open problem MEE solved, now [L22],
- open problem THUE NUMBER solved, now [GT22],

[^0]- added open problem [O9] THUE CHROMATIC NUMBER,
- added open problem [08] STRONG CHROMATIC NUMBER,
- added [L21] $\exists \exists$ !-3SAT,
- added [GT21] UNIQUE $k$-LIST COLORABILITY,
- added open problem [O7] THUE NUMBER,
- added [GT20] PEBBLING NUMBER,

## 1 Introduction

In this paper we have compiled a Garey/Johnson-style list of complete problems in the polynomialtime hierarchy, at the second level and above. For optimization problems, we also include any known hardness of approximation results. This list is based on a thorough, but not infallible, literature search. We should also point out that we have not verified all of the quoted results. We realize that the list is incomplete (and will in all likelihood remain so), but we are planning on regularly updating it, as further problems come to our attention.

Definitions relevant to specific problems are contained in the list below. We briefly review the definition of the polynomial hierarchy ( $\mathbf{P H}$ ). $\mathbf{P H}$ is defined recursively from the classes $\mathbf{P}$ and NP by:

$$
\begin{aligned}
\Sigma_{0}^{\mathrm{p}} & =\Pi_{0}^{\mathrm{p}}=\mathbf{P} \\
\Sigma_{\mathbf{i}}^{\mathrm{p}} & =\mathbf{N P}^{\Sigma_{\mathrm{i}-1}^{\mathrm{p}}} \\
\Pi_{\mathbf{i}}^{\mathrm{p}} & =\operatorname{coNP}^{\Pi_{\mathrm{i}-1}^{\mathrm{p}}}
\end{aligned}
$$

where $\mathbf{c o N P}=\{\bar{L}: L \in \mathbf{N P}\}$.
In the next three sections we list problems complete for the second level of $\mathbf{P H}$, problems complete for the third level of $\mathbf{P H}$, and a selection of problems in $\mathbf{P H}$ whose complexity remains open. We should mention that there are natural problems complete for higher levels in nonclassical logics. Within each section the problems are categorized by area, and individual problems are labeled in Garey/Johnson style (e.g., GT3 for the third graph theory problem). We distinguish optimization problems by an asterisk at the beginning of their label.

## 2 The Second level

### 2.1 Logic

[L1] $\forall \exists$ 3SAT
Given: Boolean formula $\varphi(x, y)$ in 3-CNF.

Question: Is it true that $(\forall x)(\exists y) \varphi(x, y)$ ?
Reference: Stockmeyer [75], Wrathall [88].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete. Remains $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete if $\varphi$ is representable by a planar circuit (Gutner [28]). Stockmeyer and Wrathall showed that deciding QSAT ${ }_{k}$, the set of true formulas with $k-1$ quantifier alternations beginning with an $\exists$ quantifier, is $\boldsymbol{\Sigma}_{\mathbf{k}}^{\mathrm{p}}$-complete. Earlier, Meyer and Stockmeyer [56] had shown that QUANTIFIED BOOLEAN FORMULAE, the problem of deciding the truth of quantified Boolean formulas (without restriction on the number of alternations), is PSPACE-complete. See MINMAX SAT for the optimization variant.

## [L2] NOT-ALL-EQUAL $\forall \exists$ 3SAT

Given: 3-CNF formula $\varphi(x, y)$.
Question: Is it true that for every truth-assignment to $x$ there is a truth-assignment to $y$ such that each clause in $\varphi(x, y)$ contains both a true and a false literal?
Reference: Eiter, Gottlob [21].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete.

## [*L3] MONOTONE MINIMUM WEIGHT WORD

Given: A $\Pi_{1}$ nondeterministic circuit $C$ that accepts a nonempty monotone set (although $C$ may contain NOT gates) and an integer $k$. A $\Pi_{1}$ nondeterministic circuit is an ordinary Boolean circuit with two sets of inputs $x$ and $y$. We say that $C$ accepts an input $x$ iff $(\forall y) C(x, y)=1$. A monotone set is a subset $S$ for which $x \in S$ implies $x^{\prime} \in S$ for all $x^{\prime} \succeq x$, where $\succeq$ is the bitwise partial order on bitstrings.
Question: Does $C$ accept an input $x$ with at most $k$ ones?
Reference: Umans [81].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete. Also $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{P}}$-hard to approximate to within $n^{1-\epsilon}$, where $n$ is the size of circuit $C$ [81, 78]. The generalized version with $m$ sets of inputs $x$ and $y_{1}, y_{2}, \ldots, y_{m-1}$ in which $C$ accepts an input $x$ iff $\left(\forall y_{1}\right)\left(\exists y_{2}\right)\left(\forall y_{3}\right) \ldots C\left(x, y_{1}, y_{2}, \ldots y_{m-1}\right)$ is $\boldsymbol{\Sigma}_{\mathbf{m}}^{\mathbf{p}}$-complete and $\boldsymbol{\Sigma}_{\mathbf{m}}^{\mathbf{p}}$-hard to approximate to within $n^{1-\epsilon}[83,78]$. Maximization version of MONOTONE MAXIMUM ZEROS.

## [*L4] MONOTONE MAXIMUM ZEROS

Given: A $\Pi_{1}$ nondeterministic circuit $C$ that accepts a nonempty monotone set (although $C$ may contain NOT gates) and an integer $k$. See MONOTONE MINIMUM WEIGHT WORD above for the relevant definitions.
Question: Does $C$ accept an input $x$ with at least $k$ zeros?
Reference: Umans [83].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete. Also $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-hard to approximate to within $n^{1 / 8-\epsilon}$, where $n$ is the size of circuit $C$. The generalized version with $m$ sets of inputs $x$ and $y_{1}, y_{2}, \ldots, y_{m-1}$ in
which $C$ accepts an input $x$ iff $\left(\forall y_{1}\right)\left(\exists y_{2}\right)\left(\forall y_{3}\right) \ldots C\left(x, y_{1}, y_{2}, \ldots y_{m-1}\right)$ is $\boldsymbol{\Sigma}_{\mathbf{m}}^{\mathbf{p}}$-complete and $\boldsymbol{\Sigma}_{\mathbf{m}}^{\mathbf{p}}$-hard to approximate to within $n^{1 / 8-\epsilon}$. Minimization version of MONOTONE MINIMUM WEIGHT WORD.

## [L5] GENERALIZED 3-CNF CONSISTENCY

Given: Two sets $A$ and $B$ of Boolean formulas.
Question: Is there a Boolean formula $\varphi$ such that $\varphi \wedge \psi$ is satisfiable for all $\psi \in A$, and unsatisfiable for all $\psi \in B$ ?
Reference: Ko, Tzeng [44].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete. Similar in structure to PATTERN CONSISTENCY, and GRAPH CONSISTENCY.

## [*L6] MIN DNF

Given: A DNF formula $\varphi$ and an integer $k$. The size of a formula is the number of occurrences of literals in the formula.

Question: Is there a DNF formula $\psi$ such that $\psi \equiv \varphi$ and $\psi$ has size at most $k$ ?
Reference: Umans [84].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete. Also $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-hard to approximate to within $n^{1 / 4-\epsilon}$ (resp., $n^{1 / 3-\epsilon}$ ), where $n$ is the size of $\varphi$ (resp., $n$ is the number of terms in $\varphi$ ) [81, 83, 78]. The variant in which the size is the number of terms is also $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-complete, and $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-hard to approximate to within the same factors. The problem is also known as MEE $_{\text {DNF }}$, and MIN. If we drop the restriction to DNF formulas, we obtain MEE. The complexity of the variant MINIMAL is not known.

## [*L7] IRREDUNDANT

Given: A DNF formula $\varphi$ and an integer $k$.
Question: Is there a subset of at most $k$ terms from $\varphi$ whose disjunction is equivalent to $\varphi$ ?
Reference: Umans [81].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-complete. Also $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-hard to approximate to within $n^{1 / 4-\epsilon}$ (resp., $n^{1 / 3-\epsilon}$ ), where $n$ is the number of occurrences of literals in $\varphi$ (resp., $n$ is the number of terms in $\varphi$ ) [81, 83, 78]. Minimization version of MAXIMUM TERM DELETION. The variant in which $\varphi$ is a 3 -DNF tautology is called MIN DNF TAUTOLOGY and remains $\boldsymbol{\Sigma}_{2^{-}}^{\mathrm{p}}$ complete $[24,70]$, and $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{P}}$-hard to approximate to within $n^{\epsilon}[70]$.

## [*L8] MAXIMUM TERM DELETION

Given: A DNF formula $\varphi$ and an integer $k$.
Question: Can one delete at least $k$ terms from $\varphi$ so that the remaining DNF is equivalent to $\varphi$ ?
Reference: Umans [83].

Comments: $\mathbf{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete. Also $\mathbf{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-hard to approximate to within $n^{\epsilon}$ for some constant $\epsilon>0$, where $n$ is the number of occurrences of literals in $\varphi$ [83, 78]. Maximization version of IRREDUNDANT.

## [*L9] SHORT CNF

Given: A DNF formula $\varphi$ and an integer $k$ in unary. The size of a formula is the number of occurrences of literals in the formula.

Question: Is there a CNF formula $\psi$ such that $\psi \equiv \varphi$ and $\psi$ has size at most $k$ ?
Reference: Schaefer, Umans [70].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete. Also $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-hard to approximate to within a factor $n^{\epsilon}$, where $n$ is the size of $\varphi$. The problem was proposed by Papadimitriou [61, Problem 17.3.12].

## [*L10] SHORTEST IMPLICANT CORE

Given: A DNF formula $\varphi$, an implicant $C$ of $\varphi$, and an integer $k$. An implicant of $\varphi$ is a set of literals whose conjunction implies $\varphi$. The size of an implicant is its size as a set.

Question: Is there an implicant $C^{\prime} \subseteq C$ of $\varphi$ of size at most $k$ ?
Reference: Umans [84].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete. Also $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-hard to approximate to within $n^{1-\epsilon}$, where $n$ is the number of occurrences of literals in $\varphi$ [81, 78]. Minimization version of MAXIMUM LITERAL DELETION.

## [*L11] MAXIMUM LITERAL DELETION

Given: A DNF formula $\varphi$, an implicant $C$ of $\varphi$, and an integer $k$. See SHORTEST IMPLICANT CORE above for the relevant definitions.

Question: Is there a subset $D \subseteq C$ of size at least $k$ for which $C^{\prime}=C \backslash D$ is an implicant of $\varphi ?$
Reference: Umans [83].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete. Also $\mathbf{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-hard to approximate to within $n^{\epsilon}$ for some constant $\epsilon>0$, where $n$ is the number of occurrences of literals in $\varphi[83,78]$. Minimization version of SHORTEST IMPLICANT CORE.

## [*L12] SHORTEST IMPLICANT

Given: A Boolean circuit $\varphi$, and an integer $k$.
Question: Is there an implicant $C$ of $\varphi$ of size at most $k$ ? See SHORTEST IMPLICANT CORE above for the relevant definitions.

Reference: Umans [84].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete. Also $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-hard to approximate to within $n^{1-\epsilon}$, where $n$ is the number of occurrences of literals in $\varphi$. The variant in which $\varphi$ is a Boolean formula remains $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-complete and $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-hard to approximate to within the same factor [82]. The
variant in which $\varphi$ is a DNF formula is complete for a class between coNP and $\boldsymbol{\Sigma}_{2}^{\mathbf{p}}$ called $\mathbf{G C}\left(\log ^{2} n, \mathbf{c o N P}\right)$ [84], and $\mathbf{G C}\left(\log ^{2} n, \mathbf{c o N P}\right)$-hard to approximate to within an $(1 / 3-\epsilon) \log n$ additive factor, where $n$ is the number of terms in $\varphi$ [83].

## [L13] CIRCUIT RESTRICTION

Given: Two circuits $C_{1}$ and $C_{2}$ on the same set of variables $V$. Two circuits are equivalent if they compute the same truth-table on $V$. A restriction of a circuit is obtained by setting some of the variables to constant values in $\{0,1\}$.
Question: Is $C_{1}$ a restriction of $C_{2}$ ?
Reference: Borchert, Ranjan [7].
Comments: $\Sigma_{2}^{\mathrm{p}}$-complete. Three other variants are also $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete: allowing variables to be renamed, allowing variables to be set and renamed, or replacing variables by literals [7]. If variables are renamed bijectively, the problem turns into BOOLEAN ISOMORPHISM which is likely to be intermediary between the first and second level of the hierarchy $[1,8]$.

## [*L14] MINMAX SAT

Given: 3-CNF formula $\varphi(x, y)$ and integer $k$.
Question: For every truth-assignment to $x$, is there a truth-assignment to $y$ making at least $k$ clauses in $\varphi(x, y)$ true?
Reference: Meyer, Stockmeyer [56].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete. Optimization version of $\forall \exists 3$ SAT. Let us call $f(\varphi)$ the largest $k$ such that for every $x$ there exists a $y$ making at least $k$ clauses in $\varphi(x, y)$ true. Then there is a $c>0$ such that approximating $f(\varphi)$ to within a factor of $c$ is $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-hard. This follows from work on debate systems (generalizing the PCP characterization of NP) [13, 41] as pointed out in [42]. Ko and Lin [43] showed that the $c$-approximation problem remains $\Pi_{2}^{\mathrm{p}}$-hard if the number of occurrences of each variable is bounded by a constant $B$ (MINMAX SAT B). This result is used in the proof that LONGEST DIRECTED CIRCUIT is $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete. Havev, Regev, and Ta-Shma [33] showed that MINMAX SAT B remains $\Pi_{2}^{\mathrm{p}}$-complete, even if we know that in positive instances all clauses are true.

## [L15] $\exists^{*} \forall^{*}$ SATISFIABILITY IN FOL WITH ONE UNARY FUNCTION

Given: A first-order formula $\varphi$ whose quantifier part is of the form $\exists^{*} \forall^{*}$, where $\varphi$ may contain equality and one unary function, but no other constant, function, or relation symbols.
Question: Is there a model for $\varphi$ ?
Reference: Börger, Grädel, Gurevich [9, Theorem 6.4.19].
Comments: $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete; the harder part being membership in $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$. This is a special case of Ramsey's decidability result of the satisfiability problem for $\exists^{*} \forall^{*}$ formulas with equality, but no other relation symbols (which is NEXP-complete). The following variants of the satisfiability problem are also $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete: quantifier part of the form $\exists^{*} \forall^{*}$, and no relation or function symbols except for equality; quantifier part of the form $\exists^{*} \forall^{*}$, and at most one unary relation (no function symbols, no equality); quantifier part of the form $\exists^{2} \forall^{*}$, and relations of arbitrary arity (no functions, no equality). See [9, Theorem 6.4.7]. Also, see $\exists^{*} \forall^{*}$ CNF SATISFIABILITY WITH EQUALITY.

## [L16] $\exists^{*} \forall^{*}$ CNF SATISFIABILITY WITH EQUALITY

Given: A first-order formula $\varphi$ whose quantifier part is of the form $\exists^{*} \forall^{*}$, and whose quantifierfree part is in 3 -CNF and may contain equality, but no function, or relation symbols.
Question: Is there a model for $\varphi$ of cardinality three?
Reference: Pichler [63].
Comments: $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete. Remains $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete if cardinality is any fixed integer at least three. See $\exists^{*} \forall^{*}$ SATISFIABILITY IN FOL WITH ONE UNARY FUNCTION.

## [L17] CONSTRAINTS OVER PARTIALLY SPECIFIED FUNCTIONS

Given: A set of partially specified Boolean functions $f_{1}, \ldots, f_{n}$, and a Boolean formula $\varphi$ over $f_{1}, \ldots, f_{n}$. A partially specified Boolean function $f$ is a circuit with three output values: 1,0 , and $d$ (for "don't care").
Question: Can the "don't care" values in $f_{1}, \ldots, f_{n}$ be set to 0 and 1 such that $\varphi$, when interpreted over the resulting Boolean functions, is always true?

Reference: Sriram, Tandon, Dasgupta, Chakrabarti [73].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete.

## [L18] $\exists \forall \exists \exists$ PRESBURGER ARITHMETIC

Given: A first-order formula $\varphi$ of Presburger arithmetic, that is, allowing addition and equality, whose quantifier part is of the form $\exists \forall \exists \exists$.
Question: Is $\varphi$ true in the natural numbers?
Reference: Schöning [72].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete. Truth in Presburger Arithmetic of formulas with prefix $\exists_{1} \forall_{2} \ldots \forall_{m} \exists^{3}$ is $\boldsymbol{\Sigma}_{\mathbf{m}}^{\mathbf{p}}$-complete if $m$ is even, and the truth of formulas with prefix $\exists_{1} \forall_{2} \ldots \exists_{m} \exists^{3}$ is $\boldsymbol{\Sigma}_{\mathbf{m}^{-}}^{\mathbf{p}}$ complete if $m$ is odd. The $\exists \forall$ case is NP-complete.

## [L19] GRAPH SATISFIABILITY

Given: 3-CNF formula $\varphi$. With a formula $\varphi$ we associate a graph $G(\varphi)$ on the variables and clauses of $\varphi$ with an edge between a variable and a clause, if the variable occurs in the clause (positively, or negatively). We call $\varphi$ graph-satisfiable if every $\psi$ with $G(\varphi)=G(\psi)$ is satisfiable (i.e. the satisfiability of $\varphi$ only depends on the graph $G(\varphi)$ ).
Question: Is $\varphi$ graph satisfiable?
Reference: Szeider [76, 77].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete. For 2-CNF formulas graph satisfiability can be recognized in linear time. Reduction from 2-COLORING EXTENSION.

## [L20] ARGUMENT COHERENCE

Given: Digraph (without self-loops) $H=(X, A)$, called an argument system. $X$ is the set of arguments, and $A$ the set of attacks; we say $x$ attacks $y$ if $(x, y) \in A$. An argument $x \in X$ is attacked by $S \subseteq X$ if $(y, x) \in A$ for some $y \in S$. A set of arguments $S$ is conflict-free if no argument in $S$ is attacked by $S$. An argument $x \in X$ is acceptable with respect to $S$ if for every $y \in X$ that attacks $x$ there is a $z \in S$ that attacks $y$. A set of arguments $S$ is admissible if every argument in $S$ is acceptable with respect to $S$. A preferred extension is a maximal admissible set. A stable extension $S$ is a conflict free set that attacks every argument in $\bar{S} . H$ is coherent if every preferred extension is stable.
Question: Is $H$ coherent?
Reference: Dunne, Bench-Capon [17].
Comments: $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete. The proof also shows that the question of whether a given argument occurs in every preferred extension is $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete as well.

## [L21] ヨヨ!-3SAT

Given: 3-CNF formula $\varphi$. " $\exists$ !" is interpreted as "there is exactly one".
Question: Is $\exists x \exists!y \varphi(x, y)$ true?
Reference: Marx [52].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-complete. Used to show UNIQUE $k$-LIST COLORABILITY $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-complete.

## [*L22] MINIMUM EQUIVALENT EXPRESSION

Given: A well-formed Boolean formula $\varphi$, integer $k$. The size $|\varphi|$ of a formula is the number of occurrences of literals in the formula.

Question: Is there a well-formed Boolean formula $\psi$ for which $\psi \equiv \varphi$, and $|\psi|<k$ ?
Reference: Buchfuhrer, Umans [10]. Mentioned as an open problem in Garey, Johnson [25].
Comments: $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete under Turing-reductions [10] if all Boolean formulas are over signature $\{\mathrm{V}, \wedge, \neg\}$; trivially hard for coNP, and hard for $\mathbf{P}_{\|}^{\mathbf{N P}}$ ( $\mathbf{P}$ with parallel access to NP) as shown by Hemaspaandra and Wechsung [35]. $\mathrm{MEE}_{d}$, the problem restricted
to $\{\vee, \wedge, \neg\}$-Boolean formulas of depth at most $d$ is also $\boldsymbol{\Sigma}_{2}^{\mathbf{p}}$-complete under Turing reductions for any fixed $d \geq 3$ [10]. Completeness under many-one reductions of MEE and $\mathrm{MEE}_{d}$ is open, as is the original version suggested by Garey, Johnson with Boolean formulas over signature $\{\vee, \wedge, \neg, \rightarrow\}$. Restricted to DNF formulas, the problem is MIN DNF, which is $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete. Also see MINIMAL.

## [L23] $\exists \exists!$ ! $\mathbf{t}$-3SAT

Given: 3-CNF formula $\varphi(x, y)$ with a proper partial assignment over $y$. A partial assignment over $S$ assigns truth-values to a subset of the $S$-variables. It is proper if every clause in $\varphi$ contains a true literal. An assignment assigns truth-values to all variables in the formula. It respects a partial assignment, if it agrees with the truth-values of the partial assignment.
Question: Is $\exists x \exists!_{t} y \varphi(x, y)$ true? That is, is there a partial assignment $t^{\prime}$ over $x$ so that there is a unique proper assignment of $\varphi$ which respects $t^{\prime}$ ?
Reference: Hatami, Maserrat [31].
Comments: $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete. Used to show MINIMUM 3SAT DEFINING SET $\boldsymbol{\Sigma}^{\mathrm{p}}$-complete.

## [L24] MINIMUM 3SAT DEFINING SET

Given: 3-CNF formula $\varphi$, integer $k$. A defining set is a partial assignment of truth-values to variables of $\varphi$ which has a unique extension to a satisfying assignment of $\varphi$. The size of a defining set is the number of variables that are assigned truth-values.
Question: Does $\varphi$ have a defining set of size at most $k$ ?
Reference: Hatami, Maserrat [31].
Comments: $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete. Reduction from $\exists \exists_{t}!$ 3SAT. Used to show MINIMUM VERTEX COLORING DEFINING SET $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-complete.

### 2.2 Graph Theory

## [GT1] GRAPH CONSISTENCY

Given: Two sets $A$ and $B$ of (finite) graphs.
Question: Is there a graph $G$ such that every graph in $A$ is isomorphic to a subgraph of $G$, but no graph in $B$ is isomorphic to a subgraph of $G$ ?
Reference: Ko, Tzeng [44] (GRAPH RECONSTRUCTION).
Comments: $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete. Similar in structure to PATTERN CONSISTENCY, and GENERALIZED 3-CNF CONSISTENCY.

## [*GT2] MINMAX CLIQUE

Given: Graph $G=(V, E)$, a partition $\left(V_{i, j}\right)_{i \in I, j \in J}$ of $V$, integer $k$. For a function $t: I \rightarrow J$ let $f_{t}$ be the size of the largest clique in $G$ restricted to $\bigcup_{i \in I} V_{i, t(i)}$.
Question: Is $\min _{t \in J^{I}} f_{t}(G) \geq k$ ?

Reference: Ko, Lin [42].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete. There is a $c>0$ such that approximating $f_{t}(G)$ to within a factor $c$ is $\Pi_{2}^{\mathrm{p}}$-hard. Also see MAXMIN VERTEX COVER.

## [*GT3] MINMAX CIRCUIT

Given: Graph $G=(V, E)$, a partition $\left(V_{i, j}\right)_{i \in I, j \in J}$ of $V$, integer $k$. For a function $t: I \rightarrow J$ let $f_{t}$ be the length of the longest cycle in $G$ restricted to $\bigcup_{i \in I} V_{i, t(i)}$.
Question: Is $\min _{t \in J^{I}} f_{t}(G) \geq k$ ?
Reference: Ko, Lin [42].
Comments: $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete. It is not known whether the $c$-approximation version of this problem remains $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete.

## [GT4] DYNAMIC HAMILTONIAN CIRCUIT

Given: Graph $G=(V, E)$, subset $B$ of $E$. For a subset $D$ of $E$, define $G_{D}=(V, E-D)$.
Question: Is it true that for all $D \subseteq B$ with $|D| \leq|B| / 2, G_{D}$ has a Hamilton cycle.
Reference: Ko, Lin [42].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete.

## [*GT5] LONGEST DIRECTED CIRCUIT

Given: Directed graph $G=(V, E)$, and a subset $E^{\prime}$ of $E$ of alterable edges, integer $k$. For $D \subseteq E$ let $G_{D}$ be the graph obtained from $G$ by substituting each edge $(u, v)$ in $D$ by its reverse edge $(v, u)$. Define $f_{D}$ to be the length of the longest cycle in $G_{D}$.
Question: Is $l(G)=\min _{D \subseteq E^{\prime}} f_{D} \geq k$ ?
Reference: Ko, Lin [43].
Comments: $\boldsymbol{\Pi}_{\mathbf{2}}^{\mathbf{p}}$-complete. There is a constant $c>0$ such that approximating $l(G)$ to within a factor of $c$ is $\boldsymbol{\Pi}_{2}^{\mathbf{p}}$-hard.

## [GT6] SUCCINCT TOURNAMENT REACHABILITY

Given: Circuit $C$ representing a tournament graph $G=(V, E)$ (i.e., $C(u, v)=1$ if and only if $(u, v) \in E)$, and two vertices $s, t$. A tournament graph has exactly one edge between each pair of vertices.
Question: Is $t$ reachable from $s$ in $G$ ?
Reference: Nickelsen, Tantau [79, 60].
Comments: $\boldsymbol{\Pi}_{\mathbf{2}}^{\mathrm{p}}$-complete. The more interesting part is showing that the problem lies in $\boldsymbol{\Pi}_{\mathbf{2}}^{\mathrm{p}}$. Remains in $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$ for graphs of bounded independence number (instead of tournaments); a generalization of this variant lies in $\boldsymbol{\Pi}_{\mathbf{3}}^{\mathbf{p}}$, but is not known to be complete. The variant of the tournament problem in which $G$ must be strongly connected is also $\Pi_{2}^{\mathrm{p}}$-complete.
[*GT7] SUCCINCT TOURNAMENT DOMINATING SET

Given: Circuit $C$ representing a tournament graph $G=(V, E)$ (i.e., $C(u, v)=1$ if and only if $(u, v) \in E$ ), and an integer $k$. A tournament graph has exactly one edge between each pair of vertices.

Question: Does $G$ have a dominating set of size at most $k$ ? A dominating set is a subset $V^{\prime} \subseteq V$ such that every vertex is reachable in zero or one steps from $V^{\prime}$.
Reference: Umans [83].
Comments: $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete. Also $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-hard to approximate to within $n^{1 / 2-\epsilon}$, where $n$ is the size of the circuit $C$ [83, 78]. The nonsuccinct version is considered in [62].

## [GT8] 3-COLORING EXTENSION

Given: Graph $G$.
Question: Can any 3-coloring of the leaves of $G$ be extended to a 3 -coloring of all of $G$ ?
Reference: Ajtai, Fagin, Stockmeyer [2].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete, even if $G$ has maximum degree at most 4. The general version of the problem has two players alternating in $k$ rounds with vertices of degree $i$ being colored in round $i<k$, and all remaining vertices colored in round $k$. This last player wins, if he can complete a legal coloring. This problem is $\boldsymbol{\Sigma}_{\mathbf{k}}^{\mathrm{p}}$-complete if $k$ is odd, and $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete if $k$ is even, even if the graph has maximum degree at most $\max \{k, 4\}$. Also see 2-COLORING EXTENSION.

## [GT9] GENERALIZED GRAPH COLORING

Given: Graphs $F, G$.
Question: Is there a two-coloring of the vertices of $F$ which does not contain a monochromatic $G$ as a subgraph?
Reference: Rutenburg [64].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-complete even if $G$ is restricted to be complete. The completeness proof also works for other coNP-complete families of graphs, see, for example, the GENERALIZED NODE DELETION problem. For edge colorings compare to ARROWING and STRONG ARROWING.

## [ ${ }^{*}$ GT10] GENERALIZED NODE DELETION

Given: Graphs $F, G$, integer $k$.
Question: Can we remove at most $k$ vertices from $F$ such that the resulting graph does not contain $G$ as a subgraph?
Reference: $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-completeness is claimed in Rutenburg [64] without proof.
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-complete even if $G$ is restricted to be complete. No nonapproximability results are known.

## [GT11] GENERALIZED RAMSEY NUMBER

Given: Graph $F$, a partial two-coloring of the edges of $F$, integer $k$.
Question: Does every two-coloring of $F$ which extends the given two-coloring contain a clique on $k$ vertices.

Reference: Ko, Lin [42]. A proof can also be found in [16].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete. See also ARROWING.

## [GT12] ARROWING

Given: Graphs $F, G$, and $H$.
Question: Does $F \rightarrow(G, H)$, i.e., does every edge-coloring of $F$ with colors red and green contain either a red $G$, or a green $H$ as a subgraph?
Reference: Schaefer [67].
Comments: $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete even if $G$ is a fixed tree on at least three vertices, and $H$ a complete graph. The problem is coNP-complete for fixed three-connected graphs $G$ and $H$ [12]. If $F$ is a complete graph, then the problem is NP-hard [11], but not known to be $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete. $K_{n} \rightarrow\left(K_{m}, K_{\ell}\right)$ is unlikely to be $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete, since it lies in coNPLOGCLIQUE, where LOGCLIQUE is the problem of deciding whether a graph $F$ has a clique of size at least $\log |F|$. This version is particularly interesting since it corresponds to computing Ramsey numbers. Also see STRONG ARROWING, and GENERALIZED RAMSEY NUMBER. The vertex-coloring version of this problem is called GENERALIZED GRAPH COLORING.

## [GT13] STRONG ARROWING

Given: Graphs $F, G$, and $H$.
Question: Does $F \hookrightarrow(G, H)$, i.e. does every edge-coloring of $F$ with colors red and green contain either a red $G$, or a green $H$ as an induced subgraph of $F$ ?

Reference: Schaefer [67].
Comments: $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete if $G$ is a fixed star $K_{1, p}(p \geq 2)$, and $H$ a complete graph, or $G=H=K_{1, n}$ (the diagonal case). The noninduced version $F \rightarrow\left(K_{1, n}, K_{1, m}\right)$ is in P [12]. Also see ARROWING.

## [GT14] 2-COLORING EXTENSION

Given: Graph $G$, set of vertices $S$.
Question: Can any 2-coloring of $S$ be extended to a 3-coloring of $G$ ?
Reference: Szeider [76].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete. Reduction from NAE $\exists \exists 3$ SAT. Used to show GRAPH SATISFIABILITY $\Pi_{2}^{\mathrm{p}}$-complete. Also see 3-COLORING EXTENSION.
[GT15] BIPARTITE GRAPH (2,3)-CHOOSABILITY

Given: Bipartite graph $G$, function $f: V \rightarrow\{2,3\} . G$ is called $f$-choosable, if for every assignment of $f(v)$ colors to each node $v$, one color can be chosen for each node to obtain a proper coloring; that is, a coloring in which adjacent vertices have different colors.
Question: Is $G f$-choosable?
Reference: Attributed to Rubin in Erdős, Rubin, Taylor [22].
Comments: $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete. Remains $\boldsymbol{\Pi}_{\mathbf{2}}^{\mathrm{p}}$-complete if $G$ is restricted to be planar (Gutner [28]). Also see LIST CHROMATIC NUMBER.

## [*GT16] LIST CHROMATIC NUMBER

Given: Graph $G$, integer $k$. $G$ is called $k$-choosable, if for every assignment of $k$ colors to every node, one color can be chosen for each node to obtain a proper coloring; that is, a coloring in which adjacent vertices have different colors. The list chromatic number, $\chi_{\ell}(G)$, also known as the choice number of $G$ is the smallest $k$ such that $G$ is $k$-choosable.
Question: Is $\chi_{\ell}(G) \leq k$ ?
Reference: Gutner, Tarsi [29].
Comments: $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete for any fixed $k \geq 3$. Reduction from $\operatorname{BIPARTITE} \operatorname{GRAPH}(2,3)$ CHOOSABILITY. Remains $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete if $G$ is bipartite. For $k=2$, the problem is solvable in polynomial time using a result of Erdős, Rubin, Taylor [22]. Gutner [28] shows that the following planar versions of the problem remain $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete: determining whether a planar triangle-free graph is 3 -choosable, determining whether a planar graph is 4-choosable, determining whether a union of two forests (on a shared vertex set) is 3 -choosable. Also see BIPARTITE GRAPH (2,3)-CHOOSABILITY and UNIQUE $k$-LIST COLORABILITY.

## [*GT17] GROUP CHROMATIC NUMBER

Given: Graph $G=(V, E)$, integer $k$. For a fixed Abelian group $A, G$ is said to be $A$-colorable if for every orientation of the edges of $G$, and every edge-labelling $\phi: E \rightarrow A$, there is a vertex-coloring $c: V \rightarrow A$, such that $\phi(u, v) \neq c(u)-c(v)$ for all directed edges $(u, v)$ of $G$. The group chromatic number $\chi_{g}(G)$ is the smallest number $\ell$ such that $G$ is $A$-colorable for all Abelian groups of order at least $\ell$.
Question: Is $\chi_{g}(G) \leq k$ ?
Reference: Král' [46]. Also in Král' and Nejedlý [47].
Comments: $\boldsymbol{\Pi}_{\mathbf{2}} \mathbf{p}$-complete for any fixed $k \geq 3$. Also see GROUP CHOOSABILITY.

## [GT18] GROUP CHOOSABILITY

Given: Graph $G=(V, E)$, integer $\ell$. For a fixed Abelian group $A, G$ is said to be $A-\ell$ choosable if for every orientation of the edges of $G$, every list assignment $L: V \rightarrow\binom{A}{\ell}$, and every edge-labelling $\phi: E \rightarrow A$, there is a vertex-coloring $c: V \rightarrow A$ with $c(u) \in L(u)$, such that $\phi(u, v) \neq c(u)-c(v)$ for all directed edges $(u, v)$ of $G$.

Question: Is $G A$ - $\ell$-choosable?
Reference: Král' and Nejedlý [47].
Comments: $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete for any fixed group $A$ of order at least 3 and any fixed $\ell \geq 3$. In particular, it is $\Pi_{2}^{\mathrm{p}}$-complete to decide whether $G$ is $A$-colorable (also in [46]). The problem becomes polynomial-time solvable if $\ell \leq 2$. GROUP CHOOSABILITY generalizes LIST CHROMATIC NUMBER. Also see the closely related GROUP CHROMATIC NUMBER.

## [*GT19] CLIQUE COLORING

Given: Graph $G=(V, E)$, integer $k$. A $k$-clique-coloring is a function $c: V \rightarrow\{1, \ldots, k\}$ such that every maximal clique of $G$ contains two vertices of different color.
Question: Does $G$ have a $k$-clique-coloring?
Reference: Marx [51].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete for any fixed $k \geq 2$. A $k$-clique-coloring of $G$ is not necessarily a $k$-clique-coloring of the subgraphs of $G$. The variant HEREDITARY CLIQUE COLORING, in which the graph and all its induced subgraphs are required to be $k$-clique colorable turns out to be $\boldsymbol{\Pi}_{3}^{\mathrm{p}}$-complete. CLIQUE CHOOSABILITY is another $\boldsymbol{\Pi}_{3}^{\mathrm{p}}$-complete variant.

## [*GT20] PEBBLING NUMBER

Given: Graph $G=(V, E)$, integer $k$. Vertices of the graph can contain pebbles. A pebbling move along an edge $u v \in E$ removes two pebbles from $u$ and adds one pebble to $v$. The pebbling number $\pi(G)$ is the smallest number $k$ of pebbles such that for all distributions of $k$ pebbles on $G$ and for all target vertices $v \in V$ there is a sequence of pebbling moves that places a pebble on $v$.
Question: Is $\pi(G) \leq k$ ?
Reference: Milans, Clark [57].
Comments: $\boldsymbol{\Pi}_{\mathbf{2}}^{\mathrm{p}}$-complete. Remains $\boldsymbol{\Pi}_{\mathbf{2}}^{\mathrm{p}}$-complete for a single target vertex which is part of the input. Determining the optimal pebbling number, $\hat{\pi}(G)$, the smallest number $k$ of pebbles such that there is a distribution of $k$ pebbles on $G$ such that for every target vertex $v \in V$ there is a sequence of pebbling moves that places a pebble on $v$, is NPcomplete. The complexity of deciding $\pi(G)=|V|$ remains open (note that $\pi(G) \geq|V|$ ).

## [*GT21] UNIQUE $k$-LIST COLORABILITY

Given: Graph $G=(V, E)$, integer $k$. A $k$-list coloring $L$ assigns $k$ colors to each node of $G$. The graph is $L$-colorable if there is a proper coloring of the graph such that every vertex $v$ is assigned a color from its list $L(v)$. A graph is $k$-list colorable (or $k$-choosable) if there is a $k$-list coloring $L$ such that $G$ is $L$-colorable. A graph is uniquely $k$-list colorable if there is a $k$-list coloring $L$ such that there is exactly one $L$-coloring of $G$.
Question: Is $G$ uniquely $k$-list colorable?

Reference: Marx [52].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-complete. Reduction from $\exists \exists!$-3SAT. Remains $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-complete for $k=3$ or if each of the lists contains 2 or 3 elements. Can be decided in polynomial time for $k=2$ (Mahdian and Mahmoodian, see [52]). Also, see LIST CHROMATIC NUMBER.

## [*GT22] THUE NUMBER

Given: A graph $G=(V, E)$, integer $k$. A word $w$ is square-free (or non-repetitive) if there are no $u, v, w$ such that $w=u v v w$ (with $v$ not the empty word). A non-repetitive $k$-edge coloring of $G$ is a $k$-edge coloring of $G$ such that for any path in $G$, the sequence of colors along the path is square-free. The smallest $k$ such that $G$ has a non-repetitive $k$-edge coloring is called the Thue number of $G$.
Question: Is the Thue number of $G$ at most $k$ ?
Reference: Manin [50].
Comments: $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete. Deciding whether a given edge coloring is non-repetitive is coNPcomplete. If we only have to avoid non-repetitive sequences up to a certain length, the problem is NP-complete. Thue number was first defined in Alon, Grytczuk, Hauszczak, Riordan [4]. Named after Axel Thue who proved that there are infinite square-free words. Also see THUE CHROMATIC NUMBER (open problems).
[*GT23] GRAPH SANDWICH PROBLEM FOR $\Pi$
Given: Graphs $F, F^{\prime}$ so that $F \subseteq F^{\prime}$.
Question: Is there a graph $G$ satisfying $\Pi$ so that $F \subseteq G \subseteq F^{\prime}$ ?
Reference: Schaefer [69].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete for the property of being $P_{k}$-free where $k=\Theta\left(|V(G)|^{1 / 2}\right)$. Open whether there is a natural property $\Pi$, such as being well-covered, for which problem is $\Sigma_{2}^{\mathrm{p}}$-complete.

## [GT24] MINIMUM VERTEX COLORING DEFINING SET

Given: Graph $G$, integer $k$. A defining set for a vertex coloring is a partial vertex coloring which has a unique extension to a legal vertex coloring of $G$. The size of a defining set is the number of vertices colored.
Question: Does $G$ have a vertex coloring defining set of size at most $k$ ?
Reference: Hatami, Maserrat [31].
Comments: $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete for vertex 3 -colorings. Reduction from MINIMUM 3SAT DEFINING SET. For a discussion on the relationship to the forcing chromatic number, see [30].

## [*GT25] SUCCINCT $k$-DIAMETER

Given: Circuit $C$ representing a directed graph $G=(V, E)$ (i.e., $C(u, v)=1$ if and only if $(u, v) \in E)$. The diameter of a directed graph is the largest distance between any two vertices of the graph. The distance between two vertices is the length of a smallest directed path between the vertices.

Question: Does $G$ have diameter at most $k$ ?
Reference: Hemaspaandra, Hemaspaandra, Tantau, Watanabe [34].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete for any fixed $k \geq 2$. Remains $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-complete for tournaments (directed graphs for which there is exactly one edge between any two vertices) and undirected graphs [80]. Also see SUCCINCT $k$-DIAMETER and SUCCINCT $k$-RADIUS.

## [*GT26] SUCCINCT $k$-KING

Given: Circuit $C$ representing a directed graph $G=(V, E)$ (i.e., $C(u, v)=1$ if and only if $(u, v) \in E)$, integer $k$. A vertex is a $k$-king is every vertex in the graph can be reached by a directed path of length at most $k$.
Question: Does $G$ contain a $k$-king?
Reference: Hemaspaandra, Hemaspaandra, Tantau, Watanabe [34].
Comments: $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete for any fixed $k \geq 2$. Remains $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete for tournaments (directed graphs for which there is exactly one edge between any two vertices). Also see SUCCINCT $k$-KING and SUCCINCT $k$-DIAMETER.

### 2.3 Sets and Partitions

## [*SP1] SUCCINCT SET COVER

Given: A collection $S=\left\{\varphi_{1}, \varphi_{2}, \ldots, \varphi_{m}\right\}$ of 3 -DNF formulas on $n$ variables, and an integer $k$.

Question: Is there a subset $S^{\prime} \subseteq S$ of size at most $k$ for which $\vee_{\varphi \in S^{\prime}} \varphi \equiv 1$ ?
Reference: Umans [81].
Comments: $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete. Also $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-hard to approximate to within $n^{1-\epsilon}$, where $n$ is the number of occurrences of literals in $\varphi_{1}, \varphi_{2}, \ldots, \varphi_{m}[81,78]$. The restriction in which all the $\phi_{i}$ except $\phi_{1}$ are single literals, and $\phi_{1}$ evaluates to 1 on at least $1 / 2$ of the domain remains $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-complete and $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-hard to approximate to within the same factor. This restriction can be seen as a succinct version of RICH HYPERGRAPH COVER [83], whose complexity was considered in [62].

## [SP2] GENERALIZED SUBSET SUM

Given: Two vectors $u$ and $v$ of integers, and an integer $t$.
Question: Is $(\exists x)(\forall y)[u x+v y \neq t]$ true, where the variables $x$ and $y$ are binary vectors of the same length as $u$ and $v$ ?
Reference: Berman, Karpinski, Larmore, Plandowski, Rytter [6].
Comments: $\Sigma_{2}^{\mathrm{p}}$-complete. Used to show FULLY COMPRESSED TWO-DIMENSIONAL PATTERN MATCHING $\Pi_{2}^{\mathrm{p}}$-complete.
[*SP3] MAXMIN VERTEX COVER

Given: Graph $G=(V, E)$, a partition $\left(V_{i, j}\right)_{i \in I, j \in J}$ of $V$, integer $k$. For a function $t: I \rightarrow J$ let $f_{t}$ be the size of a smallest vertex cover of $G$ restricted to $\bigcup_{i \in I} V_{i, t(i)}$.
Question: Is $\max _{t \in J^{I}} f_{t}(G) \leq k$ ?
Reference: Ko, Lin [42].
Comments: $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-completeness follows from $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-completeness of MINMAX CLIQUE using the standard transformation between vertex covers and cliques. The nonapproximability result for MINMAX CLIQUE does not carry over, and no nonapproximability results are currently known.

## [*SP4] MINMAX THREE DIMENSIONAL MATCHING

Given: Set $W$, partition $\left(W_{i, j}\right)_{i \in I, j \in J}$ of $W$, set $S$ of three-element subsets of $W$, and an integer $k$. Call a set $S^{\prime} \subseteq S$ a matching in $W^{\prime} \subseteq W$, if the sets in $S^{\prime}$ are mutually disjoint subsets of $W^{\prime}$. For a function $t: I \rightarrow J$ let $f_{t}(W)$ be the size $\left|S^{\prime}\right|$ of a largest matching $S^{\prime}$ in $\bigcup_{i \in I} W_{i, t(i)}$.
Question: Is $\min _{t \in J^{I}} f_{t}(W) \geq k$ ?
Reference: Ko, Lin [42].
Comments: $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete; reduction from MINMAX SAT YB. There is a $c>0$ such that approximating $\min _{t \in J^{I}} f_{t}(W)$ to within a factor $c$ is $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-hard.

## [SP5] $\forall \exists$ THREE DIMENSIONAL MATCHING

Given: Three disjoint sets $X_{1}, X_{2}, X_{3}$ of the same cardinality, and two disjoint subsets $M_{1}$ and $M_{2}$ of $X_{1} \times X_{2} \times X_{3}$. A matching of $X_{1}, X_{2}, X_{3}$ is a set $S \subseteq X_{1} \times X_{2} \times X_{3}$ of size $\left|X_{1}\right|=\left|X_{2}\right|=\left|X_{3}\right|$ such that the components of the elements of $S$ contain all the elements of $X_{1} \cup X_{2} \cup X_{3}$.
Question: For any subset $S_{1}$ of $M_{1}$, is there a subset $S_{2}$ of $M_{2}$ such that $S_{1} \cup S_{2}$ is a matching?
Reference: McLoughlin [55].
Comments: Used to show $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-completeness of COVERING RADIUS. A gap version of this problem remains $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-hard which implies $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-hardness of approximation for COVERING RADIUS [27].

### 2.4 Algebra and Number Theory

## [AN1] INTEGER EXPRESSION INEQUIVALENCE

Given: Two integer expressions $e_{1}$, and $e_{2}$ built from binary numbers with operators + , and $\cup$. For an integer expression $e$ define $L(e)=\{n\}$ if $e$ is the binary representation of $n$, $L(e+f)=\{n+m: n \in L(e), m \in L(f)\}$, and $L(e \cup f)=L(e) \cup L(f)$.
Question: Is $L\left(e_{1}\right) \neq L\left(e_{2}\right)$ ?
Reference: Stockmeyer, Meyer [25]. The result appears in a 1973 conference paper by Stockmeyer and Meyer, and a 1976 paper by Stockmeyer.

Comments: $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete. Probably the first natural problem to be shown $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete. The subset problem $L\left(e_{1}\right) \subseteq L\left(e_{2}\right)$ is $\boldsymbol{\Pi}_{\mathbf{2}}^{\mathbf{p}}$-complete. The same is true for expressions represented in the general hierarchy input language (GHIL) which according to Wagner [87] was shown by Bentley, Ottmann, and Widmayer (1983). Huynh [39] observes that his result that 1 LETTER TERMINAL ALPHABET GRAMMAR INEQUIVALENCE is $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete implies that deciding the inequivalence of integer expressions over a unary alphabet with operations $\cup, \cdot,{ }^{2}$, and ${ }^{*}$ is also $\Sigma_{2}^{\mathrm{p}}$-complete. See INTEGER EXPRESSION CONNECTEDNESS, and INTEGER EXPRESSION COMPONENT LENGTH.

## [AN2] INTEGER EXPRESSION CONNECTEDNESS

Given: An integer expression $e$ built from binary numbers with operators +, and $\cup$. See INTEGER EXPRESSION INEQUIVALENCEabove for the definition of an integer expression. A set of integers $S$ is called connected if for every $x, z \in S$ and any $y$, if $x<y<z$ then $y \in S$.

Question: Is $L(e)$ connected?
Reference: Wagner [87].
Comments: $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete. The result also holds if the input is specified using the general hierarchic input language (GHIL).

## [*AN3] BOOLEAN EXPRESSION COMPONENT LENGTH

Given: A Boolean formula $\varphi$, integer $k$. If $\varphi$ has $n$ Boolean input variables $x_{1}, \ldots, x_{n}$ we let $L(\varphi)=\left\{x_{1} \cdots x_{n}: \varphi\left(x_{1}, \ldots, x_{n}\right)\right\}$ interpreting the binary vector as a natural number. A set of numbers $L$ is called connected if for every $x, z \in L$ and any $y$, if $x<y<z$ then $y \in L$. A maximal connected subset of a set is called a component.
Question: Does $L(\varphi)$ have a component of size at least $k$ ?
Reference: Wagner [87].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-complete. For integer expressions the problem is $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathrm{p}}$-complete (INTEGER EXPRESSION COMPONENT LENGTH). No nonapproximability results are known.

## [AN4] BOUNDED EIGENVECTOR

Given: $n \times n$ integer matrix $M$, eigenvalue $\lambda$ of $M$, subset $I \subseteq\{1, \ldots, n\}$, rational number $y$.
Question: Is there an eigenvector $\mathbf{x}=\left(x_{1}, \ldots, x_{n}\right)$ (for $\lambda$ ) such that $x_{1}=y,\left|x_{i}\right| \leq c$ (for some fixed $c$ ), and $\mathbf{x}$ has maximal $\ell_{2}$-norm among vectors identical to $\mathbf{x}$ on $I$ ?
Reference: Eiter, Gottlob [21].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{P}}$-complete for any fixed $c \geq 1$, and $y=0$.

## [AN5] SEMILINEAR SET EQUIVALENCE

Given: Finite sets $C_{i}, P_{i}, C_{i}^{\prime}, P_{i}^{\prime} \subseteq \mathbb{N}^{k}(1 \leq i \leq n)$. Let $L(C, P)=\left\{c+\sum_{p \in P} \lambda_{p} p: c \in C, p \in\right.$ $P, \lambda \in \mathbb{N}\}$, and $S L\left(C_{1}, \ldots, C_{n} ; P_{1}, \ldots P_{n}\right)=\bigcup_{i=1}^{n} L\left(C_{i}, P_{i}\right)$. Sets of the form $L$ are called linear, sets of the form $S L$ semilinear.

Question: Is $S L\left(C_{1}, \ldots, C_{n} ; P_{1}, \ldots P_{n}\right)=S L\left(C_{1}^{\prime}, \ldots, C_{n}^{\prime} ; P_{1}^{\prime}, \ldots P_{n}^{\prime}\right)$ ?
Reference: Huynh [40].
Comments: $\boldsymbol{\Pi}_{\mathbf{2}}^{\mathrm{p}}$-complete, even for $k=1$.

### 2.5 Automata and Languages

## [AL1] PATTERN CONSISTENCY

Given: Two sets $A$ and $B$ of strings over $\{0,1\}$. A pattern is a string over $\{0,1\}$ and a set of variables. The language $L(p)$ associated with a pattern $p$ is the set of strings that can be obtained from $p$ by substituting all variables in $p$ by strings over $\{0,1\}$.
Question: Is there a pattern $p$ such that $A \subseteq L(p) \subseteq \bar{B}$.
Reference: Ko, Tzeng [44].
Comments: $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete. Similar in structure to GRAPH CONSISTENCY, and GENERALIZED 3-CNF CONSISTENCY.

## [AL2] FULLY COMPRESSED TWO-DIMENSIONAL PATTERN MATCHING

Given: Two images succinctly represented by straight-line programs. One image is called the pattern, the other the text. A straight-line program is a sequence of instructions of types $A \leftarrow B \oslash C$ (put image $B$ next to image $C$ if images have same height), and $A \leftarrow B \ominus C$ (put image $B$ on top of image $C$ if images have same width). Terminal symbols are 0 and 1.

Question: Is the pattern contained in the text (as a subrectangle)?
Reference: Berman, Karpinski, Larmore, Plandowski, Rytter [6].
Comments: $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete. Reduction from GENERALIZED SUBSET SUM. The fully compressed pattern matching problem for strings (one-dimensional patterns) can be solved in polynomial time (see [65] for a survey on compressed pattern matching).

## [AL3] 1LTA GRAMMAR INEQUIVALENCE

Given: Two context-free grammars $G_{1}$ and $G_{2}$ over a 1-letter terminal alphabet. Let $L(G)$ be the language generated by a grammar $G$.
Question: Is $L\left(G_{1}\right) \neq L\left(G_{2}\right)$ ?
Reference: Huynh [39].
Comments: $\Sigma_{2}^{\mathrm{p}}$-complete. Reduction from INTEGER EXPRESSION INEQUIVALENCE. The more difficult part here is showing that the problem lies in $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$ by using a variant of Parikh's theorem. The result has consequences for a unary variant of INTEGER EXPRESSION INEQUIVALENCE.
[AL4] POMSET LANGUAGE CONTAINMENT

Given: Two POMSETS $P, Q$. A POMSET (partially ordered multiset) is a directed acyclic graph $(V, E)$ whose vertices have labels in $\Sigma$. The language $L(P)$ associated with a POMSET $P$ is the set of words of length $n=|V|$ over $\Sigma$ that corresponds to a permutation of the vertices in $V$ which is consistent with the partial order generated by $(V, E)$.
Question: Is $L(P) \subseteq L(Q)$ ?
Reference: Feigenbaum, Kahn, Lund [23].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete. The language membership problem is NP-complete, and determining the size of $L(P)$ is span-P complete. Determining whether $L(P)=L(Q)$ obviously lies in $\boldsymbol{\Pi}_{\mathbf{2}}^{\mathrm{p}}$, and Feigenbaum, Kahn, and Lund showed that it is at least as hard as GRAPH ISOMORPHISM.
[AL5] STAR-FREE REG. EXPRESSION W/ INTERLEAVING EQUIVALENCE

Given: Two regular expressions $e_{1}, e_{2}$ using union, concatenation, and interleaving. For two words $x, y \in\{0,1\}^{*}$ the operation $\mid$ of interleaving $x$ and $y$ results in the set $x \mid y$ containing all words $x_{1} y_{1} \ldots x_{k} y_{k}$ such that $x=x_{1} \ldots x_{k}$, and $y=y_{1} \ldots y_{k}$, where the $y_{i}$ can have any length (including zero).
Question: Are $e_{1}$ and $e_{2}$ equivalent, i.e., do they describe the same set of words?
Reference: Mayer, Stockmeyer [54].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete. The proof is based on Stockmeyer's INTEGER EXPRESSION INEQUIVALENCE result. There are many versions of the regular expression problem. The standard version has union, concatenation, and Kleene star, and it is PSPACEcomplete [25, AL9]. Adding interleaving, or intersection (Hunt, 1973; according to [54]) makes it exponential space-complete. Removing both the Kleene star and interleaving gives an NP-complete problem (Hunt, Stockmeyer and Mayer, 1973; according to [54]).

## [AL6] TRIE 2

Given: A sequence $\Pi$ of patterns of length $n$ and an integer $k$. A pattern is a string in $\{0,1, *\}^{*}$. A call is a string over $\{0,1\}$ ( $*$ matches both 0 and 1 ). A TRIE $T$ is an ordered rooted tree (i.e. the order of a depth-first search traversal is specified) whose edges have labels in $\{1,2, \ldots\} \times\{0,1, *\}$. A TRIE $T$ for $\Pi$ is a TRIE which has as many leaves as $\Pi$ has patterns. Furthermore if $\tau$ is the set of labels along the path to the $j$ th leaf reached in the fixed depth-first search traversal of $T$, then $\tau$ needs to be equal to the $j$ th pattern in $\Pi$ (for all $j$ ). For a call $c$ let $m(c, T)$ be the number of edges that a depth-first traversal of $T$ will visit (we do not continue along an edge whose label is not consistent with $c$ ). Intuitively $m(c, T)$ is the number of matches performed by the TRIE to find all patterns in $\Pi$ matching $c$.
Question: Is there a call $c$ such that $m(c, T) \geq k$ for all TRIEs $T$ for $\Pi$.
Reference: Lin [49].

Comments: $\Pi_{2}^{\mathbf{p}}$-complete. There is a constant $0<c<1$ for which approximating $f(\Pi)=$ $\min _{T} \max _{c} m(c, T)$ to within a factor of $c$ is $\boldsymbol{\Pi}_{\mathbf{2}}^{\mathrm{p}}$-hard. For a fixed TRIE the problem is NP-complete (Dawson, Ramakrishnan, Ramakrishnan, Swift, 1994; according to [49]).

## [AL7] BOOLEAN ALGEBRA UNIFICATION

Given: Two terms $\phi$ and $\psi$ over a Boolean algebra (operations,$+ \times, \neg$ and constants 0,1 ) with free constants.

Question: Can $\phi$ and $\psi$ be unified; that is, is there a substitution $\sigma$ of the free constants by terms of the Boolean algebra such that $\sigma(\phi)$ and $\sigma(\psi)$ are congruent in the Boolean algebra?
Reference: Baader [5].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete. Is NP-complete, if free constants are not allowed.

## [AL8] SIMPLE XPATH CONTAINMENT

Given: Simple XPath expressions $P_{1}$ and $P_{2}$. The application of a simple XPath expression $P$ to an XML document results in a set of nodes (of the XML document). We write $P_{1} \subseteq P_{2}$ if for all XML documents the nodes returned by $P_{1}$ are contained in the set of nodes returned by $P_{2}$. For precise definitions see [14] and references mentioned there.
Question: Does $P_{1} \subseteq P_{2}$ ? hold?
Reference: Deutsch, Tannen [14].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete, as are several variants of the problem.

## [AL9] TRACE MONOID PRESENTATION

Given: Two trace monoids $M=M(A, D)$, and $M^{\prime}=M\left(A, D^{\prime}\right)$ such that $D \subseteq D^{\prime}$. A trace monoid $M(A, D)$ is a set of traces, that is, the quotient set $A^{*} /\{a b=b a \mid(a, b) \notin D\}$ of equivalence classes of words over the (finite) alphabet $A$, where two words are equivalent if one can be transformed into the other by repeatedly transposing pairs of letters ( $a, b$ ) not in $D$. The dependence relation $D$ is required to be reflexive and symmetric. A trace replacement system for a trace monoid $M=M(A, D)$ is a subset $R$ of $M \times M$. An element $(l, r)$ or $R$ is considered as a rewriting rule $l \Rightarrow r$ over $M . R$ is called complete if it is Noetherian (no infinite chains), and confluent.
Question: Is there a finite, complete trace replacement system $R$ such that $M / R=M^{\prime}$ ?
Reference: Diekert, Ochmański, Reinhardt [15].
Comments: $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete. The paper also shows that a similar question about semi-commutation systems is equivalent, and therefore also $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete.

## [AL10] PLANAR NET DEADLOCK

Given: A nondeterministic finite automaton $A$, and an integer $n$. We construct a planar cellular automaton by placing $n^{2}$ copies of $A$ on the $n^{2}$ grid points of an $n \times n$ square grid. Neighboring automata communicate by sending and receiving messages. A deadlock
occurs if a group of automata permanently enter a waiting state (that is, they wait to receive a message which never arrives). An input to the network is a binary string of length $n$ whose $i$ th bit is sent to the $i$ th automaton in the first row.
Question: Does the cellular automaton enter a deadlock in at most $n$ time steps, for any possible input?
Reference: Durand, Fabret [18].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete. Reduction from FINITE TILING EXTENSION. Recognizing whether a network enters a deadlock in at most $n$ steps for a given input is, of course, NPcomplete.

### 2.6 Databases

## [D1] MONOTONIC RELATIONAL EXPRESSION CONTAINMENT

Given: Two monotonic relational expressions $e_{1}$, and $e_{2}$, i.e. only using operators select, project, join, and union. We write $\nu_{D}(e)$ to denote the extension of the relational expression $e$ for a particular database state $D$.
Question: Is $e_{1}$ contained in $e_{2}$; that is, is it true that $\nu_{D}\left(e_{1}\right) \subseteq \nu_{D}\left(e_{2}\right)$ for all database states $D$ ?
Reference: Sagiv, Yannakakis [66].
Comments: $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete. Implies that testing equivalence of monotonic relational expressions is also $\Pi_{2}^{\mathrm{p}}$-complete.

## [D2] RESTRICTED RELATIONAL EXPRESSION CONTAINMENT (INEQ)

Given: Two restricted relational expressions $e_{1}$, and $e_{2}$, i.e. only using operators select, project, and join. The select conditions are allowed to contain inequalities $(\leq,<, \neq)$. We write $\nu_{D}(e)$ to denote the extension of the relational expression $e$ for a particular database state $D$.

Question: Is $e_{1}$ contained in $e_{2}$; that is, is it true that $\nu_{D}\left(e_{1}\right) \subseteq \nu_{D}\left(e_{2}\right)$ for all database states $D$ ?
Reference: van der Meyden [85].
Comments: $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete. Remains $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete if only one type of inequality ( $\leq,<$, or $\neq$ ) is allowed in the select conditions [85]. It also remains $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete, if the expressions are assumed to be safe (only variables that occur as arguments of relations can appear in inequalities), and certain other conditions (see [45]). Becomes coNP-complete, if all relations are unary. Without inequalities, the problem is NP-complete.

## [D3] DISJUNCTIVE DATABASE LITERAL INFERENCE

Given: A disjunctive database $D$, and a literal $w$. A disjunctive database is a collection of formulas of the form $a_{1} \vee \ldots \vee a_{n} \leftarrow b_{1} \wedge \ldots \wedge b_{k} \wedge \bar{b}_{k+1} \wedge \ldots \wedge \bar{b}_{m}$ where the $a_{i}$ and $b_{j}$ are variables. There are different notions of $D \models w$ depending on the semantics chosen.

Question: Does $D \models w$ ?
Reference: Eiter, Gottlob [20].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete for the following semantics: (Extended) Generalized Closed World Assumption, Extended Closed World Assumption, Iterated Closed World Assumption, Perfect Model Semantics, and Disjunctive Stable Semantics. It remains $\boldsymbol{\Pi}_{\mathbf{2}}^{\mathrm{p}}$-complete in all these cases, if the formulas of the disjunctive database do not contain negation, and there are no integrity clauses (i.e. $n>0$ in all formulas). The problem is $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-hard, and in $\mathbf{P}^{\Pi_{2}^{P}}[O(\log n)]$ for the Careful Closed World Assumption.

## [D4] DISJUNCTIVE DATABASE MODEL EXISTENCE

Given: A disjunctive database $D$, and a literal $w$. A disjunctive database is a collection of formulas of the form $a_{1} \vee \ldots \vee a_{n} \leftarrow b_{1} \wedge \ldots \wedge b_{k} \wedge \bar{b}_{k+1} \wedge \ldots \wedge \bar{b}_{m}$ where the $a_{i}$ and $b_{j}$ are variables. There are different semantics for what it means to be a model of $D$.
Question: Is there a model for $D$ ?
Reference: Eiter, Gottlob [20].
Comments: $\Pi_{2}^{\mathrm{p}}$-complete for Perfect Model Semantics, and Disjunctive Stable Semantics.

### 2.7 Games and Puzzles

## [GP1] STRONG NASH EQUILIBRIUM

Given: A game $\mathcal{G}$ in graphical normal form. A game $\mathcal{G}$ consists of a set $P$ of players, and, for every player, a set of neighbors $N(p) \subseteq P-\{p\}$, a set of actions $A(p)$, and a utility function $u_{p}: \times_{x \in N(p) \cup\{p\}} A(x) \rightarrow \mathbb{R}$. The game is in graphical normal form, if the utility function of each player is represented as a table. For a collection of players $P^{\prime} \subseteq P$, an element of $\times_{p \in P^{\prime}} A(p)$ is called a strategy. A strategy is global, if $P^{\prime}=P$. A global strategy $x$ is called a strong Nash equilibrium if there is no collection of players $P^{\prime}$ for whom there is a strategy $y \in \times_{p \in P^{\prime}} A(p)$ which would strictly increase all of their gains; i.e. for all $p \in P^{\prime}$ we would have $u_{p}(x)<u_{p}(x \mid y)$, where by $x \mid y$ we denote the strategy which on $P^{\prime}$ agrees with $y$, and with $x$ otherwise.
Question: Does $\mathcal{G}$ have a strong Nash equilibrium?
Reference: Gottlob, Greco, Scarello [26].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-complete. Strong Nash equilibria generalize the notion of pure Nash equilibria whose definition is similar, but instead of arbitrary collection of players only requires local optimality for singleton sets of players. Deciding the existence of pure Nash equilibria is NP-complete.

## [GP2] FINITE TILING EXTENSION

Given: A finite set $C$ of $c$ colors (including a blank color), a tile set $T \subseteq C^{4}$, an integer $n$. We say the four sides of the tile $(t, r, b, l)$ are colored $t$ (top), $r$ (right), $b$ (bottom), $l$ (left). In a tiling of the plane tiles cannot be rotated or reversed. In a legal tiling, any two adjacent tiles must meet in the same color.

Question: Is there a legally tiled row $R$ of $n$ tiles which cannot be extended to a legal tiling of an $n \times n$ square such that $R$ is the first row of that square and the square is surrounded by blank tiles?

Reference: Durand, Fabret [18]. Also see van Emde Boas [86]. The finite tiling variant of the problem, in which we ask whether an $n \times n$ square can be tiled using the tiles in $T$ is NP-complete. This result is attributed to many different authors in different sources, including Lewis (in [86]), Garey, Johnson, and Papadimitriou (in [25]). The ideas for the reduction go back to papers by Robinson, Wang, and Berger (see [86]). The same reduction gives the $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{p}}$-completeness result for FINITE TILING EXTENSION. However, it seems that Durand and Fabret were the first authors to make this observation explicitly in print (they actually attribute the result to van Emde Boas).
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-complete. There are many versions of the tiling problem; for a detailed discussion see the survey by van Emde Boas [86]. Durand and Fabret use the tiling problem to show that PLANAR NET DEADLOCK is $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete.

### 2.8 Coding and Cryptography

## [ $\left.{ }^{*} \mathrm{CC} 1\right]$ COVERING RADIUS

Given: A linear code, given by a binary parity-check matrix $H$ of dimensions $m \times n$, integer $r$. The code associated with $H$ is the set $C=\left\{\mathbf{x}: \mathbf{x} H^{t}=\mathbf{0}\right\}$. The covering radius of the code $C$ is $\rho=\max _{\mathbf{x} \in\{0,1\}^{n}} \min _{\mathbf{c} \in C} d(\mathbf{x}, \mathbf{c})$, where $d(\mathbf{x}, \mathbf{c})$ is the Hamming distance between $\mathbf{x}$ and $\mathbf{c}$.
Question: Is $\rho \leq r$ ?
Reference: McLoughlin [55].
Comments: $\boldsymbol{\Pi}_{2}^{\mathbf{p}}$-complete. Reduction from $\forall \exists$ THREE DIMENSIONAL MATCHING. $\mathbf{\Pi}_{2}^{\mathbf{p}}$-hard to approximate to within some constant factor $c<2$; however it can be approximated to within a factor of 2 in $\mathbf{A M}$ [27].

## [*CC2] IDENTIFYING LINEAR CODE

Given: A linear code, given by a binary parity-check matrix $H$ of dimensions $m \times n$, integer $r$. The code associated with $H$ is the set $C=\left\{\mathbf{x}: \mathbf{x} H^{t}=\mathbf{0}\right\} . C$ is called $r$-identifying, if the sets $B_{r}(\mathbf{x}) \cap C$ are all nonempty and pairwise different for $x \in\{0,1\}^{n}$.

Question: Is $C$ an $r$-identifying code?
Reference: Honkala, Lobstein [36].
Comments: $\boldsymbol{\Pi}_{2}^{\mathbf{p}}$-complete. Reduction from $\forall \exists$ THREE DIMENSIONAL MATCHING and COVERING RADIUS. A code is called $r$-locating-dominating, if the sets $B_{r}(\mathbf{x}) \cap C$ are all nonempty and pairwise different for $x \notin C$. Deciding, whether $C$ is $r$-locating-dominating is also $\boldsymbol{\Pi}_{\mathbf{2}} \mathbf{p}$-complete.

### 2.9 Miscellaneous

[*M1] MINIMUM BLOCK ENCODER AND DECODER
Given: Directed graph $G$, integers $p, q, k_{1}$, and $k_{2} . G$ is a $D I F$, that is, it is a strongly connected graph whose edges are labeled with 0 and 1 such that every vertex has at most one outgoing edge of each label. Define $S(G)$ to be the set of all binary strings that can be obtained by following a directed path in $G$. A DIF $G$ is called block-feasible, if there is a set $C \subseteq\{0,1\}^{q}$ of size at least $2^{p}$ whose closure is contained in $S(G)$; that is, there are $2^{p}$ codewords fulfilling the constraints described by $G$. A circuit $D$ computing an injective function $\{0,1\}^{p} \rightarrow C$ is called an encoder, a circuit $E$ computing an injective function $C \rightarrow\{0,1\}^{p}$ is called an decoder. The size of a circuit is the number of gates in the circuit.
Promise: $G$ is block-feasible.
Question: Is there a decoder $D$ of size at most $k_{1}$, and an encoder of size at most $k_{2}$ ?
Reference: Stockmeyer, Modha [74].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}{ }^{\mathrm{p}}$-complete under randomized reduction. MINIMUM BLOCK DECODER is $\boldsymbol{\Sigma}_{\mathbf{3}^{-}}^{\mathrm{p}}$ complete, and the complexity of MINIMUM BLOCK ENCODER is open.

## [M2] PETRI NET MARKING EQUIVALENCE

Given: Petri nets $\left(N_{1}, M_{1}\right),\left(N_{2}, M_{2}\right)$ which share the same set of places. The two nets are called marking equivalent if they have the same set of reachable markings. The Petri nets are assumed to be sinkless and normal, or conflict-free.
Question: Are $\left(N_{1}, M_{1}\right)$ and $\left(N_{2}, M_{2}\right)$ marking equivalent?
Reference: Howell, Rosier [37], and Howell, Rosier, Yen [38].
Comments: The general problem is undecidable (Rabin), but it is $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete if the Petri nets are sinkless and normal [38], or conflict-free [37]. The problem remains complete if instead of equivalence we ask for containment.

## [M3] CONSTRAINT RANKING

Given: A regular set $X \subseteq\{0,1\}^{m}$, given by a finite automaton, called attested surface set, and a collection of constraints $\left\{C_{1}, \ldots, C_{n}\right\}$. A constraint $C$ of an attested surface set $X$ is a function from $X$ to the natural numbers (also computed by a finite automaton). A ranking of the constraints is an ordering $\vec{C}$ of $\left\{C_{1}, \ldots, C_{n}\right\}$. An element $x$ of $X$ is consistent with a ranking $\left(C_{i_{1}}, \ldots, C_{i_{n}}\right)$ if $\left(C_{i_{1}}(x), \ldots, C_{i_{n}}(x)\right) \leq_{\text {lex }}\left(C_{i_{1}}(y), \ldots, C_{i_{n}}(y)\right)$ for all $y \in\{0,1\}^{m}$, where $\leq_{\text {lex }}$ is the lexicographical ordering.
Question: Is there an $x \in X$ consistent with some ranking $\vec{C}$ of $C$ ?
Reference: Eisner [19].
Comments: $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$-complete. Learning-theory problem from phonology.

## 3 The Third Level

### 3.1 Graph Theory

## [*GT1] PATH VC DIMENSION

Given: A graph $G=(V, E)$, and a integer $k$. Let $V C_{\mathrm{path}}(G)$ be the size of the largest set $X \subseteq V$ which is shattered by subpaths of $G$, i.e. such that for each $S \subseteq X$ there is a subpath of $G$ containing all vertices in $S$, but no vertex of $X \backslash S$.
Question: Is $V C_{\text {path }}(G) \geq k$ ?
Reference: Schaefer [68].
Comments: Special case of the GRAPH VC DIMENSION problem defined for types of subgraphs of a given graph. Introduced by Kranakis, et al. [48] building on an idea of Haussler and Welzl [32]. The problem is also $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathbf{p}}$-complete for cycles instead of paths [68]. All other cases investigated so far turn out to be in $\mathbf{P}$ (stars, neighborhoods), or NP-complete (trees, connected sets) [48]. Also see VC DIMENSION and Q-ARY VC DIMENSION. No nonapproximability results are known.

## [*GT2] CLIQUE CHOOSABILITY

Given: Graph $G=(V, E)$, integer $k$. A $k$-list assignment assigns a list $L(v)$ of $k$ colors to every vertex $v$ of $G$. A $k$-clique-list-coloring chooses for every vertex $v$ a color from $L(v)$ such that every maximal clique of $G$ contains two vertices of different color. The graph is $k$-clique-choosable if there is a $k$-clique-list-coloring for every $k$-list assignment.

Question: Is $G$ a $k$-clique-choosable graph?
Reference: Marx [51].
Comments: $\Pi_{3}^{\mathrm{p}}$-complete for any fixed $k \geq 2$. The colorability version, CLIQUE COLORING is $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete. Also see HEREDITARY CLIQUE COLORING.

## [*GT3] HEREDITARY CLIQUE COLORING

Given: Graph $G=(V, E)$, integer $k$. A $k$-clique-coloring is a function $c: V \rightarrow\{1, \ldots, k\}$ such that every maximal clique of $G$ contains two vertices of different color. $G$ is hereditarily $k$-clique-colorable if there it has a $k$-coloring which is a $k$-clique-coloring for all induced subgraphs of $G$.

Question: Does $G$ have a hereditary $k$-clique-coloring?
Reference: Marx [51].
Comments: $\Pi_{3}^{\mathrm{p}}$-complete for any fixed $k \geq 3$. The complexity of the case $k=2$ remains open. Also see CLIQUE COLORING and CLIQUE CHOOSABILITY.

## [*GT4] SUCCINCT $k$-RADIUS

Given: Circuit $C$ representing a directed graph $G=(V, E)$ (i.e., $C(u, v)=1$ if and only if $(u, v) \in E)$, integer $k$. The $r$-neighborhood of a vertex is the set of vertices that are
reachable from the vertex by a path of length at most $r$. The radius of a directed graph is the radius $r$ of the smallest $r$-neighborhood that contains all of $G$.
Question: Does $G$ have radius at most $k$ ?
Reference: Hemaspaandra, Hemaspaandra, Tantau, Watanabe [34].
Comments: $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathrm{p}}$-complete for any fixed $k \geq 2$. Not known to remain $\boldsymbol{\Sigma}_{3}^{\mathrm{p}}$-complete for tournaments (directed graphs for which there is exactly one edge between any two vertices). For undirected graphs, the problem is also $\boldsymbol{\Sigma}_{3}^{\mathrm{p}}$-complete and becomes $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete for $k=1$ [80]. Also see SUCCINCT $k$-DIAMETER and SUCCINCT $k$-KING.

### 3.2 Sets and Partitions

## [*SP1] VC DIMENSION

Given: A collection $\mathcal{C}$ of subsets of a finite set $U$, represented succinctly by a Boolean circuit $C$ such that $C(i, x)=1$ if and only if element $x$ is in the $i$-th set $S_{i}$, and an integer $k$.
Question: Is $\operatorname{VC}(\mathcal{C}) \geq k$, i.e. is there a set $X \subseteq U$ of size at least $k$, such that for every $S \subseteq X$ there is an $i$ such that $S=S_{i} \cap X$ ?
Reference: Schaefer [71].
Comments: $\boldsymbol{\Sigma}_{3}^{\mathbf{p}}$-complete. Also $\boldsymbol{\Sigma}_{3}^{\mathrm{p}}$-hard to approximate to within a factor of $2-\epsilon$, but can be approximated to within a factor of 2 in $\mathbf{A M}$ [58]. If $\mathcal{C}$ is represented nonsuccinctly by a matrix the problem is LOGNP-complete as shown by Papadimitriou and Yannakakis [62]. Also see PATH VC DIMENSION and Q-ARY VC DIMENSION.

## [*SP2] Q-ARY VC DIMENSION

Given: A collection $\mathcal{C}$ of vectors in $\{1,2, \ldots q\}^{U}$, where $U$ is a finite set, represented succinctly by a Boolean circuit $C$ such that $C(i, x)$ is the $x$-th element of the $i$-th vector, and an integer $k$.
Question: Is $V C_{q}(\mathcal{C}) \geq k$, i.e. is there a set $X \subseteq U$ of size at least $k$, such that $\left\{\left(v_{x}\right)_{x \in X} \mid v \in\right.$ $\mathcal{C}\}=\{1,2, \ldots q\}^{X}$ ?
Reference: Mossel, Umans [59].
Comments: $\boldsymbol{\Sigma}_{3}^{\mathrm{p}}$-complete. Also $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathrm{p}}$-hard to approximate to within a factor of $q-\epsilon$, but can be approximated to within a factor of $q$ in AM. Also see PATH VC DIMENSION and VC DIMENSION.

### 3.3 Algebra and Number Theory

## [*AN1] INTEGER EXPRESSION COMPONENT LENGTH

Given: An integer expression $e$ built from binary numbers with operators + , and $\cup$, and a number $k$. For an integer expression $e$ define $L(e)=\{n\}$, if $e$ is the binary representation of $n, L(e+f)=\{n+m: n \in L(e), m \in L(f)\}$, and $L(e \cup f)=L(e) \cup L(f)$. A set of numbers $L$ is called connected if for every $x, z \in L$ and any $y$, if $x<y<z$ then $y \in L$. A maximal connected subset of a set is called a component.

Question: Does $L(e)$ have a component of size at least $k$ ?
Reference: Wagner [87].
Comments: $\Sigma_{3}^{\mathrm{p}}$-complete. The result also holds if using the general hierarchic input language (GHIL) for specifying the input. If the set of integers is specified by a Boolean formula, the problem is $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete (BOOLEAN EXPRESSION COMPONENT LENGTH). See INTEGER EXPRESSION INEQUIVALENCE, INTEGER EXPRESSION CONNECTEDNESS.

### 3.4 Miscellaneous

## [*M1] MINIMUM BLOCK DECODER

Given: Directed graph $G$, integers $p, q$, and $k . G$ is a DIF, that is, it is a strongly connected graph whose edges are labeled with 0 and 1 such that every vertex has at most one outgoing edge of each label. Define $S(G)$ to be the set of all binary strings that can be obtained by following a directed path in $G$. A DIF $G$ is called block-feasible, if there is a set $C \subseteq\{0,1\}^{q}$ of size at least $2^{p}$ whose closure is contained in $S(G)$; that is, there are $2^{p}$ codewords fulfilling the constraints described by $G$. A circuit $D$ computing an injective function $\{0,1\}^{p} \rightarrow C$ is called an encoder, a circuit $E$ computing an injective function $C \rightarrow\{0,1\}^{p}$ is called an decoder. The size of a circuit is the number of gates in the circuit.
Promise: $G$ is block-feasible.
Question: Is there a decoder $D$ of size at most $k$ ?
Reference: Stockmeyer, Modha [74].
Comments: $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathrm{p}}$-complete. Remains $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathbf{p}}$-complete if $p>\alpha q$ for any $\alpha<1$ and $G$ has finite memory (from a certain length onward the acceptance of each string by $G$ ends in a unique vertex only depending on the string). MINIMUM BLOCK ENCODER AND DECODER lies in $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$, and is hard for $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$ under randomized reductions. The complexity of the variant MINIMUM BLOCK ENCODER is open.

## 4 Open Problems

## [O1] RAMSEY

Given: Finite Graphs $G$, and $H$.
Question: Does $K_{n} \rightarrow(G, H)$, i.e. does every edge-coloring of $K_{n}$ with colors red and green contain either a red $G$, or a green $H$ as a subgraph.
Comments: The problem is NP-hard [11], but not known to be $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$-complete. Also see ARROWING.

## [*O2] MINIMUM EQUIVALENT EXPRESSION

Comments: Solved for $\{\vee, \wedge, \neg\}$-Boolean formulas, open over signature $\{\vee, \wedge, \neg, \rightarrow\}$. See [L22].

## [*O3] MINIMAL

Given: A well-formed Boolean formula $\varphi$. The size $|\varphi|$ of a formula is the number of occurrences of literals in the formula.

Question: There is no well-formed Boolean formula $\psi$ such that $\psi \equiv \varphi$ and $|\psi|<|\varphi|$.
Reference: Meyer, Stockmeyer [56].
Comments: coNP-hard [35], and in $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$. Also see MEE, and MIN DNF.

## [*O4] MINIMUM BLOCK ENCODER

Given: Directed graph $G$, integers $p, q$, and $k . G$ is a DIF, that is, it is a strongly connected graph whose edges are labeled with 0 and 1 such that every vertex has at most one outgoing edge of each label. Define $S(G)$ to be the set of all binary strings that can be obtained by following a directed path in $G$. A DIF $G$ is called block-feasible, if there is a set $C \subseteq\{0,1\}^{q}$ of size at least $2^{p}$ whose closure is contained in $S(G)$; that is, there are $2^{p}$ codewords fulfilling the constraints described by $G$. A circuit $D$ computing an injective function $\{0,1\}^{p} \rightarrow C$ is called an encoder, a circuit $E$ computing an injective function $C \rightarrow\{0,1\}^{p}$ is called an decoder. The size of a circuit is the number of gates in the circuit.

Promise: $G$ is block-feasible.
Question: Is there an encoder $E$ of size at most $k$ ?
Reference: Stockmeyer, Modha [74].
Comments: Lies in $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$, and is NP-hard. The similar MINIMUM BLOCK DECODER problem is $\boldsymbol{\Sigma}_{\mathbf{3}}^{\mathrm{p}}$-complete. Finding an encoder and a decoder of total size at most $k$ also lies in $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathrm{p}}$, with complexity open. Putting separate bounds on the size of decoder and encoder leads to MINIMUM BLOCK ENCODER AND DECODER which is $\boldsymbol{\Sigma}_{2}^{\mathrm{p}}$-complete under randomized reducibility.

## [O5] POMSET LANGUAGE EQUALITY

Given: Two POMSETS $P, Q$. A POMSET (partially ordered multiset) is a directed acyclic graph $(V, E)$ whose vertices have labels in $\Sigma$. The language $L(P)$ associated with a POMSET $P$ is the set of words of length $n=|V|$ over $\Sigma$ that corresponds to a permutation of the vertices in $V$ which is consistent with the partial order generated by $(V, E)$.
Question: Is $L(P)=L(Q)$ ?
Reference: Feigenbaum, Kahn, Lund [23].
Comments: In $\boldsymbol{\Pi}_{2}^{\mathrm{p}}$, and at least as hard as GRAPH ISOMORPHISM. See POMSET LANGUAGE CONTAINMENT.

## [O6] DISJUNCTIVE DATABASE FORMULA INFERENCE

Given: A disjunctive database $D$, and a formula $\varphi$. A disjunctive database is a collection of formulas of the form $a_{1} \vee \ldots \vee a_{n} \leftarrow b_{1} \wedge \ldots \wedge b_{k} \wedge \bar{b}_{k+1} \wedge \ldots \wedge \bar{b}_{m}$ where the $a_{i}$ and $b_{j}$ are variables. There are different notions of $D \models w$ depending on the semantics chosen.

Question: Does $D \models w$ ?
Reference: Eiter, Gottlob [20].
Comments: The problem is $\boldsymbol{\Pi}_{\mathbf{2}}^{\mathrm{p}}$-hard, and lies in $\mathbf{P}^{\boldsymbol{\Pi}}{ }^{\mathrm{p}}[O(\log n)]$ for the Generalized Closed World Assumption, and the Careful Closed World Assumption. If $\varphi$ is a literal, it is known to be $\boldsymbol{\Pi}_{\mathbf{2}} \mathbf{p}$-complete in the Generalized Closed World Assumption semantics.

## [*O7] THUE NUMBER

Comments: Solved. See [GT22].

## [*O8] STRONG CHROMATIC NUMBER

Given: A graph $G=(V, E)$, integer $k$. If $k$ divides $|G|$ we call $G$ strongly $k$-colorable if for every partition of $V$ into pairwise disjoint sets of size $k$ there is a proper coloring of $G$ such that every color occurs exactly once in each set of the partition. If $k$ does not divide $G$ we add at most $k$ isolated vertices to $G$ so it does. The strong chromatic number of $G$ is the smallest $k$ such that $G$ is strongly $k$-colorable.
Question: Is the strong chromatic number of $G$ at most $k$ ?
Reference: The strong chromatic number was defined by Alon [3].
Comments: In $\boldsymbol{\Pi}_{\mathbf{2}}^{\mathrm{p}}$. Alon points out that in case the graph has bounded degree and the partition is given it can be decided in polynomial time whether a strong coloring exists using Beck's effective version of the Lovasz Local Lemma.

## [*O9] THUE CHROMATIC NUMBER

Given: A graph $G=(V, E)$, integer $k$. A word $w$ is square-free (or non-repetitive) if there are no $u, v, w$ such that $w=u v v w$ (with $v$ not the empty word). A non-repetitive $k$-(vertex) coloring of $G$ is a $k$-coloring of $G$ such that for any path in $G$, the sequence of colors along the path is square-free. The smallest $k$ such that $G$ has a non-repetitive $k$-coloring is called the Thue chromatic number of $G$.
Question: Is the Thue chromatic number of $G$ at most $k$ ?
Reference: The Thue chromatic number first defined in Alon, Grytczuk, Hauszczak, Riordan [4].
Comments: In $\boldsymbol{\Sigma}_{2}^{\mathbf{p}}$. Given a 4-coloring of a graph, it is coNP-complete to decide whether it is non-repetitive [53]. Named after Axel Thue who proved that there are infinite square-free words. Also see THUE NUMBER.

Acknowledgment. Many thanks to Lane Hemaspaandra for many helpful suggestions. Thanks to Nikolay Pelov for pointing out a mistake in the statement of GENERALIZED SUBSET SUM.
