

## Computational Geometry

---

---

---

---

---

---

---

---

## Complexity Notions

- algorithm
  - time, space
  - complexity bounds
    - $O(n^2)$ , ... (upper bounds)
    - $\Omega(n \log n)$ , ... (lower bounds)
    - $\Theta(n)$ , ... (precise bounds)
    - common bounds:
      - $\log n$  (logarithmic),
      - $n$  (linear),
      - $n \log n$ ,
      - $n^2$  (quadratic),
      - $c^n$  (exponential)
- Examples:
- linear search
  - binary search
  - shortest path
  - traveling salesman
  - indexing
  - quantifier elimination

---

---

---

---

---

---

---

---

## Sorting

- Can sort  $n$  numbers in time  $O(n \log n)$ 
  - which algorithms do this? Deterministic?
  - average versus worst case complexity
- Need  $\Omega(n \log n)$ 
  - decision tree argument
- lower bounds are rare and typically apply to restricted models
- searching: preprocessing vs processing time

---

---

---

---

---

---

---

---

## Output Lower Bounds

Example: *line segment intersection*

- how many intersections can  $n$  line segments have?
- would that make a fair lower bound in all cases?
- can be done in
  - $O(n \log n + k)$  time and  $O(n)$  space,
  - where  $k = \#$  intersections
- output sensitive complexity

---

---

---

---

---

---

---

---

## Basic Data Structures

- binary search tree
  - build in time  $O(n \log n)$ , storage  $O(n)$
  - search in  $O(\log n)$(<http://webpages.ull.es/users/jriera/Docencia/AVL/AVL%20tree%20applet.htm>)
- dynamic binary search trees (red/black, AVL)
  - build in time  $O(n \log n)$ , storage  $O(n)$
  - search, insert, delete in  $O(\log n)$

---

---

---

---

---

---

---

---

## Sample Problem: Windowing a Circuit

- simplify problem: only straight horizontal/vertical lines (orthogonal layout)
- report all points/line segments with parts in the window

- naive algorithm ?
- better solution ?
- what is needed ?

---

---

---

---

---

---

---

---

## 1d Range Search

Input:  $\{x_0, \dots, x_n\}$ , points on the line,  
interval  $x, x'$

Output:  $\{x_0, \dots, x_n\} \cap [x, x']$

Data structure: binary search tree

- $O(n \log n)$  construction
- $O(n)$  space,  $O(k + \log n)$  time for query
- can be made more efficient by storing "canonical sets" of leaves

---

---

---

---

---

---

---

---

## 2d Range Search

Input:  $\{x_0, \dots, x_n\}$ , points in the plane,  
rectangle  $R := [x, x'] \times [y, y']$

Output:  $\{x_0, \dots, x_n\} \cap R$

How can we solve this ?

---

---

---

---

---

---

---

---

## kd-Tree

- alternate 1d-strategy for x/y
- split point-set at median value (divide & conquer)
- e.g. <http://homes.lieu.edu.tr/~hakcan/projects/kdtree/kdTree.html>
- what's construction time/storage?

- how long to determine whether a point belongs to the set ?

---

---

---

---

---

---

---

---

## kd-Tree

- simple implementation gives
  - $O(n \log n)$  construction
  - $O(\log n)$  point query
  - $O(n)$  storage
- what about region (rectangle) query ?

---

---

---

---

---

---

---

---

## kd-Tree range search

- simple implementation gives
  - $O(\sqrt{n} + k)$  query
    - look at horizontal/vertical lines, how many regions can they intersect
    - animations: <http://www.cs.cmu.edu/~awm/animations/kdtree/>
- can be improved to  $O(\log^2 n + k)$  using range trees and  $O(\log n + k)$  using fractional cascading, storage increased to  $O(n \log n)$

---

---

---

---

---

---

---

---

## Circuit Windowing, 1<sup>st</sup> step

- can reports all points in window
- what else ?
- what's left ?

---

---

---

---

---

---

---

---

## Interval Intersection

Input: a set of  $n$  intervals, an interval  $[x, x']$

Output: list all intervals intersecting  $[x, x']$

E.g. which English composers could Wagner (1813-1883) have met?

---

---

---

---

---

---

---

---

## Interval Intersection

- use interval tree
- intersection query for  $[x, x']$ :
  - find node  $f$  with  $f.\text{median}$  in  $[x, x']$ , let  $P$  be path from root to  $f$
  - from  $f$  continue as if running two stabbing queries for  $x$  and  $x'$ , let paths be  $Q$  and  $Q'$
  - for all nodes in  $P, Q, Q'$  report intervals containing  $x$  or  $x'$
  - for  $Q$ : report all intervals in right subtrees
  - for  $Q'$ : report all intervals in left subtrees

---

---

---

---

---

---

---

---

## General Strategies

- Incremental
- Divide & Conquer
- Line sweep
- Randomization

---

---

---

---

---

---

---

---

## (I) Convex Hull

- naïve algorithm

assume:

- test whether two line segments intersect
- test whether a point is to the right of a line segment

how to improve this approach ?

---

---

---

---

---

---

---

---

## Convex Hull (Incremental)

- incremental convex hull

- $O(n^2)$
- <http://www.cse.unsw.edu.au/~lambert/java/3d/hull.html>

how can we improve this ?

- used presorted input

- convex hull algorithm in  $O(n \log n)$
- update points of tangency on upper/lower chain

---

---

---

---

---

---

---

---

## (II) Intersection of Half-planes

- assume we can intersect two convex polygons with  $p$  and  $p'$  vertices in time  $O(p+p')$
- how do we compute the intersection of  $n$  half-planes? analyze:
  - naïve
  - divide & conquer

---

---

---

---

---

---

---

---

### (III) Rectangle Intersection

plane sweep approach

- event list (vertical line sweeping across plane)
- active elements list

what do we need to implement this plane sweep ?

---

---

---

---

---

---

---

---

---

---

### Rectangle Intersection

$L := \{\}$

for each event  $e$  in  $E$  (ordered)

if  $e$  is start of rectangle  $R$

$L := L \cup \{R\}$

report intersections of  $[R.y1, R.y2]$  with  
y-ranges of active intervals

if  $e$  is end of rectangle  $R$

$L := L - \{R\}$

Analysis

---

---

---

---

---

---

---

---

---

---

### (iv) Point Location

Given a planar map, find the face you are in.

---

---

---

---

---

---

---

---

---

---

## Point Location

partition into slabs

- time:  $O(\log n)$ , but space ?
- how can we improve storage, keeping querying time low ?

---

---

---

---

---

---

---

---

## Trapezoidation

build search structure adding segments incrementally

- x-node (white): left/right of point
- segment node (gray): above/below segment

how do we add a segment ?

---

---

---

---

---

---

---

---

## Point Location: adding a segment

- find trapezoids that intersect segment
  - use search data structure to find left end-point, follow segments to right

extend data structure and to include new trapezoids

---

---

---

---

---

---

---

---

## Point Location via Trapezoidation

- based on order of added line segments, storage and query time can vary significantly
- determining optimal order hard
- however, random order will do with high probability:
  - expected storage:  $O(n)$
  - expected construction time:  $O(n \log n)$
  - expected query time:  $O(\log n)$

---

---

---

---

---

---

---

---

## Excursion: Art Gallery

How many guards do you need to guard a museum?

---

---

---

---

---

---

---

---

## Art Gallery Theorem (Chvatal, Fisk)

Every art gallery (simple polygon) on  $n$  vertices can be guarded by  $n/3$  guards. This bound is optimal.

---

---

---

---

---

---

---

---

## Proof of Art Gallery Theorem

- triangulate (how ?)
- show that triangulated graph can be 3-colored (no two adjacent vertices have the same color)
  - hint: dual graph (the graph connected the triangles) is a tree
- select smallest color class

---

---

---

---

---

---

---

---

## Triangulation

- easy: convex polygons
- how about monotone polygons ?
- strategy:
  - split polygon into monotone polygons
  - triangulate monotone polygons

---

---

---

---

---

---

---

---

## Triangulate Monotone Polygon

---

---

---

---

---

---

---

---

## Splitting into Monotone Polygons

- construct trapezoidation
- “turn” vertex: both neighbors on same side (with respect to  $x$ ) and angle  $> 180^\circ$ .
- remove turn vertex by connecting it to other vertex in its trapezoid
